The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Jan. 29.....39.00 |
|-------------------|-------------------|

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

L. Vogelstein & Co., writing on February 2, state that statistics published by the New York Metal Exchange show Straits shipments 5235 tons, United States deliveries 3600 tons, and an increase of 966 tons in the visible supply. This is a small increase when the month's transactions are considered. The visible supplies in England, Holland, and the United States, stocks and afloat, are 17,284 tons.

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, February 9, shows a decrease in production and stocks on hand. The details are as follows:

| Pounds. |
|--|
| Stocks of marketable copper of all kinds on hand at all points in the United States, January 1, 1914.. 91,438,867 |
| Production of marketable copper in the United States from all domestic and foreign sources during January131,770,274 |

GUGGENHEIM EXPLORATION COMPANY

Results of the operations of this well known Company in 1913 may be summarized as follows:

| | 1913. | Changes. |
|-----------------------|--------------|-------------|
| Net income..... | \$ 3,353,852 | +\$ 82,102 |
| Dividends..... | 2,357,145 | + 277,815 |
| Surplus..... | 996,707 | - 195,713 |
| Previous surplus..... | 23,814,632 | + 1,192,420 |
| Total surplus..... | 24,811,339 | + 996,707 |

The net income was equal to 16.13% on the capital stock. The general balance-sheet at the end of 1913 shows the following:

| Assets: | 1913. | Changes. |
|---|--------------|-------------|
| American Smelting Securities 'A'..... | \$ 3,060,000 | -\$ 900,000 |
| Utah Copper Co..... | 9,161,767 | |
| Yukon Gold..... | 10,114,563 | + 23,375 |
| Chino Copper..... | 2,534,802 | |
| American Smelting & Refining Co..... | 4,767,265 | |
| Ray Consolidated..... | 3,245,851 | + 660,213 |
| Miscellaneous investments..... | 56,439 | + 3,429 |
| Alaska-Yukon properties and equip- | | |
| ment..... | 1,119,443 | - 24,659 |
| Furniture, fixtures, and equipment..... | 2,255 | - 54 |
| Accounts collectable..... | 5,088 | + 539 |
| Cash and demand loans..... | 11,537,164 | + 1,233,865 |
| Total..... | \$45,604,640 | +\$ 996,707 |
| Liabilities: | | |
| Capital stock..... | \$20,793,300 | |
| Surplus..... | 24,811,340 | \$ 996,707 |
| Total..... | \$45,604,640 | + 996,707 |

All of the securities in the assets, with the exception of the American Smelting Securities Co. 'A', are carried at cost.

GOLD PRODUCTION IN WESTERN AUSTRALIA

The November yield from all mines in the state was \$2,504,400, and returns from the principal producers were as follows:

| Mine. | Tonnage. | Value. | Profit. | Dividend. |
|-------------------------------|----------|-----------|----------|-----------|
| Associated..... | 10,837 | \$ 66,000 | \$ 9,700 | |

*Including the Victorious.

The Nova Scotia Steel & Coal output in 1913 was as follows:

| | Tons. |
|------------|---------|
| Coal..... | 820,000 |
| Iron..... | 73,878 |
| Steel..... | 78,379 |
| Coke..... | 100,000 |

The quantity of iron ore received at North Sydney from the Company's ore mines at Wabana, Newfoundland, during the season amounted to 130,000 tons.

IRON ORE mined in the United States in 1913 is estimated by the U. S. Geological Survey to have been between 58,000,000 and 60,000,000 long tons. The Lake Superior district supplied about 50,000,000 tons.

Company Reports

FALCON MINES, LIMITED

This Company operates a property situated 60 miles west of Gwelo, in the Blinkwater district, Rhodesia.

Development has shown a steady increase in gold values below the third level, the average figures being: No. 3, \$3.80; No. 4, \$5.60; No. 5, \$6.10; No. 6 level, \$7 per ton.

Ore reserves at June 30, 1913, showed an increase of 187,134 tons compared with the previous year. They consist of 178,622 tons of oxidized ore containing 0.71% copper and \$6.40 gold; and 638,389 tons of sulphide ore averaging 3.15% copper and \$5.57 gold, worth at present copper prices about £2,380,686. It is hoped to have the plant in operation in June, 1914.

VINDICATOR CONSOLIDATED GOLD MINING COMPANY

This Company operates at Cripple Creek, and the report covers work during 1913. The superintendent, H. P. Nagel, Jr., reported as follows: At No. 1 shaft, 73,084 tons of crude ore was produced on Company account, yielding 22,829 net tons, or 31.24% of shipping ore, of a gross gold content of \$702,119, or \$30.75 per ton. Lessees working through No. 1 shaft produced 2222 net tons, of a gross gold content of \$85,965 or \$38.69 per ton. Royalties received from the sale of this ore amounted to \$20,728. Lessees working through other shafts on the property produced 8466 net tons, of a gross gold content of \$132,273 or \$15.62 per ton. Royalties received from the sale of this ore amounted to \$16,635. Development work of a total length of 10,187 ft. was done during 1913, making a total of 192,103 ft. to date. Development of the 1600-ft. level progressed satisfactorily, and ore-shoots were opened in six veins. Other shoots were opened on the 1200, 1300, 1400, and 1500-ft. levels. The report of Fred W. Crosley, mining engineer, gives details of development work done. The cost of powder, fuse, and caps was \$25,028, used in 10,187 ft. of development. The finances of the Company are as follows:

| | |
|--|-----------|
| Gross proceeds from all ore sales (33,517 tons)..... | \$723,727 |
| Mining | 296,885 |
| Paid to lessees | 110,577 |
| Mining profits | 316,264 |
| Sundry receipts | 6,205 |
| Cash on hand January 1, 1913..... | 84,643 |
| Dividends in 1913 | 180,000 |
| Cash on hand January 1, 1913..... | 227,112 |

RAILROAD VALLEY COMPANY

This Company operates in Nevada, and has been drilling for potash in Railroad valley, Nye county. Details of some of this work were published in this journal of August 2, 1913, and at various other times. A special meeting is being held at Tonopah on February 10 to consider the situation of the Company, to receive the report of E. E. Free, the consulting geologist, to decide if further work is warranted, and to discuss other matters of importance.

The president, Victor Barndt, states that in two years over \$115,000 has been spent in searching for potash. Over 10,000 ft. of drilling was done. A considerable amount of the work was useless, but it was pioneer work. The Company was the only private interest in the United States proving or otherwise the 'dry lake' theory of buried salt deposits. Another company, the Pacific Coast Borax Co., has since started drilling in Death valley, California. In July 1913, \$15,000 was received from the sale of treasury stock, but this was spent in sinking No. 3, 4, 5, and 6 wells. In October a loan of \$4480 was obtained under certain conditions. This

was used in sinking No. 6 well deeper, putting down No. 7 well 745 ft. deep. Cold weather stopped further work early in December. While results are inconclusive, the chance of finding potash remains as good as heretofore. Mr. Barndt recommends that other land be secured and tested, and all future work be conducted by some operating concern which will work under lease at certain royalties. The authorized capital is 1,000,000 shares, of which 73,318 are in the treasury. The balance at December 31, 1913, was \$203.

The report of E. E. Free states that the practical significance of the data now at hand rests almost entirely on the gaylussite beds. These were cut in No. 2, 4, and 6 wells. The precise correlation of the beds in No. 2 and 6 is not possible. They may be variable and local, and may persist over considerable areas. It is impossible to draw a line between No. 2 and 6 beds and show them as representing the bottom of the basin at any particular time. Although this is so, there is no reasonable doubt that gaylussite series of both wells are substantially synchronous. From general deductions, two theories are possible: (1) it may be that No. 6 well is in or near the greatest depression; and (2) it

SECTION SHOWING PROBABLE POSITION OF GAYLUSSITE BEDS.

may be that the southerly dip of the gaylussite beds continues beyond No. 6, and that the deepest depression lies an unknown distance to the south. These alternative theories are shown on the accompanying cut. The beds are reasonably well established north of No. 6 well, and are shown by the solid line, while south of this well their course is uncertain, and the two possibilities are shown by the dotted line. If the first theory is true, and No. 6 is in the depression, hopes of a potash deposit must be abandoned; but if the depression is south of No. 6, the chance of finding this material is good. The drilling of No. 7 showed nothing which can be correlated with the gaylussite beds, and it seems possible that this well was beyond the edge of the deposits. Wells No. 3 and 5, $1\frac{1}{2}$ miles northeast and $1\frac{1}{2}$ miles northwest of No. 2 respectively, failed to cut any gaylussite. The gaylussite probably covers an area of several square miles, about 100 ft. thick, around wells No. 2 and 6, and if this is so, and the material is of fair purity, and if methods can be devised for mining at low cost, there is a possibility of manufacturing soda commercially. Mr. Free recommends that No. 7 well be drilled further to cut the gaylussite, or to prove that it does not extend so deep. If a southerly extension is proved, four more wells should be put down. If this is not found, further drilling should be done to determine the extent of the present deposits cut, also one or more should be drilled right through the gaylussite. For the work recommended, for either scheme, a sum of \$25,000 would be necessary, and \$5000 for contingencies.

Gaylussite, mentioned frequently in this review, is a hydrous double carbonate of calcium and sodium, having the formula $\text{Na}_2\text{CO}_3 \cdot \text{CaCO}_3 \cdot 5\text{H}_2\text{O}$. It contains 35.81% sodium carbonate, 33.78% calcium carbonate, and 30.41% water.

Recent Patents

1,071,791.—PROCESS OF TREATING ORES. Frank W. Pugsley, Pittsford, N. Y.

A process of separating metals from ores, consisting in passing minute bubbles of chlorine gas upwardly through comminuted ore suspended in a liquid not of itself capable of reacting on the ore.

1,073,928.—ORE CONCENTRATOR. Marion L. Porter, Silverton, Ohio.

A receiving tank for the mineral-impregnated liquid, collecting plates for the mineral particles arranged in the tank, a discharge pipe connected to the tank to withdraw the water therefrom and means for heating said plates to dry the concentrate.

1,073,932.—PROCESS FOR THE MANUFACTURE OF FLUORESCENT SUBSTANCES. George Rupprecht, Hamburg, Germany.

As a new article of manufacture, a fluorescent substance comprising an artificially produced basic salt of a refractory salt forming acid, and one of the earth metals of the zinc group of the periodic system, and a small percentage of a modifying agent.

1,074,088.—ELECTRODE SUPPORTING-ROD FOR ELECTROLYTIC TANKS. Peter Jensen, Perth Amboy, N. J., assignor of one-third to Leo Goldberger and one-third to John Kudrik, Perth Amboy, N. J.

An electrode suspending-rod formed from angular stock and twisted around its longitudinal axis for producing a plurality of helical edges for engaging the suspending hooks of an electrode.

1,071,838.—MAGNETIC SEPARATOR. Joseph Weatherby, New Cumberland, Pa., assignor, by mesne assignment, to Electric Ore Separator Co., New Cumberland, Pa., a corporation of Delaware.

A combination with fixed and rotary pole pieces having a vertically elongated air gap between them, of means for maintaining a body of comminuted material in rubbing contact with the movable pole piece at one side of and in proximity to the fixed pole piece and air gap between the pole pieces.

1,071,763.—ORE-TREATING PROCESS. Thomas J. Lovett, Chicago, Ill., assignor to Copper Process Co., Chicago, Ill., a corporation of South Dakota.

A gradual reduction method of treating ore containing ductile metal in fine particles, which consists in subjecting ore-lumps holding the fine particles of metal to a prolonged rub-rolling action under pressure, to simultaneously disintegrate the gangue and roll the ductile metal particles into pellets or slugs.

1,071,715.—PROCESS AND APPARATUS FOR CLASSIFYING CRUSHED ORES. William F. Deister, Fort Wayne, Ind.

Classifier having in combination, a shell having an outlet at its lower end, a diaphragm extending across the shell, means for introducing water into the shell at a point intermediate the outlet and diaphragm, the diaphragm having openings there-through for the downward movement of the solid materials and the upward flow of the water, and means for gravitally directing the solid materials into said openings.

1,073,587.—ART OF MAKING IRON AND STEEL. James R. Billings, Birmingham, Ala., assignor to Billings Process Co., Birmingham, Ala., a corporation of West Virginia.

First obtaining the metal in a molten mass, confining the mass in a suitable receptacle, then while so confined, rapidly but under regulable control, introducing and thoroughly dis-

persing through all parts of the mass carbon or carbonaceous fuel and simultaneously effecting the generation of carbon dioxide and heat by concurrently introducing and dispersing through the mass under regulable control oxygen under a pressure not greatly in excess of the ferrostatic pressure and in quantities limited to conform approximately to the amount necessary to effect substantially complete combustion of the carbon or fuel so introduced.

1,073,653.—SIEMENS-MARTIN FURNACE. Kurt Albert, Wiesbaden, Germany.

For working up masses containing iron or ferric oxide and volatile metals, the combination with a hearth chamber, air chambers and gas chambers, flues connecting the air chambers and the gas chambers with the hearth chamber; of additional independent flues leading from the hearth chamber; means for guiding the gases of combustion through said additional flues during the volatilization period of the volatile metals and a recuperator for receiving the discharged gases.

1,074,068.—ELECTROMAGNETIC ORE-SEPARATOR. Georg Rietkotter, Hagen, Germany.

A device including a frame, a shaft fixed in said frame, an opposed pair of magnets supported fixedly from said shaft, bearing brackets fixedly mounted on said shaft; a second shaft journaled in said brackets, spaced disks revolubly mounted on said first mentioned shaft, internal gears on the inner sides of said disks, other gears on the second shaft meshing with said internal gears, means to rotate one of said disks, and a cylinder removably mounted on said disks and surrounding said gears and magnets.

1,073,644.—SEPARATING TABLE AND PROCESS OF SEPARATION. Henry M. Sutton, Walter L. Steele, and Edwin G. Steele, Dallas, Texas.

A concentrating table having a pervious floor, means for reciprocating the table adapted to propel the material in a predetermined direction, an air chamber arranged under said floor, an obstruction arranged diagonally across the line of travel of the propelling movement of the material forming an obstruction of concentrate free from direct passage in the line of imparted movement, and having passages at an angle to the line of movement of the material.

1,073,820.—PRODUCTION OF PORTLAND CEMENT. Joseph W. Richards, South Bethlehem, Pa., and Walter B. Landis, Bethlehem, Pa.

Making portland cement in a single furnace operation, which consists in making up the charge of ore in an iron-ore reduction furnace having a basic lining with the raw materials for producing a lime-alumina silicate slag and with excess of limestone sufficient to produce a liquid product having the percentage composition of portland cement clinker, and generating in said furnace a sufficient temperature to reduce the ore and to cause the clinker to flow from the furnace in the liquid state.

1,071,839.—ORE CONCENTRATOR. Joseph Weatherby, New Cumberland, Pa., assignor to the Electric Ore Separator Co., New Cumberland, Pa., a corporation of Delaware.

A transversely inclined longitudinally differentially reciprocatory dressing table having incorporated therein longitudinal strips of magnetic metal and means for differentially reciprocating said table horizontally to effect stratification and separation of the material thereon in divergent paths due to the difference in specific gravity of the elements composing the material, of a fixed magnet mounted above the table and having a pole terminal with an extended face in proximity to and above the magnetic strips in the table, whereby elongated magnetic fields are formed in which the lines of force converge toward the ore supporting the surface of the table.

A Tube-Mill Test at Butte

*During the past year several interesting articles have appeared tending to prove that the pebble mill is entitled to serious consideration in connection with the fine grinding of milling ores in the process of preparing the material for the various concentration systems. The results obtained indicate that for certain sizes and certain ores, the pebble mills are superior to the Huntington or Chilean mill, and that it does not necessarily follow that grinding by means of pebbles will produce a greater percentage of the very undesirable colloidal material. There seems to be a growing belief that the small percentage of slime produced is due to the shape of the mill, and yet no definite proof is brought forward to bear out the theory. That there is some question as to the soundness of this theory, is indicated by the fact that there is an increasing tendency to lengthen the cylindrical portion of the mill without changing the dimensions of the conical portions. Such a change seems to result in an improvement in the results obtained without materially affecting the percentage of slime produced. It appears that the power and pebbles consumption per ton of ore reduced was even less in the lengthened mill.

It is of particular interest that the Butte & Superior Copper Co., Ltd., recently made a series of tests to determine which of two types of pebble mills was the better suited for regrinding its zinc ores. The material to be ground carried about 10% zinc in the form of an included grain, a portion of the zinc mineral having been roughed out on the primary rough-

TUBE-MILL USED IN TEST.

ing tables. The middlings from these roughing tables are then classified in a Richards-Janney hydraulic classifier and the material from the first two spigots, which is approximately 10 to 30 mesh, is treated on secondary roughing tables. The middling from these secondary roughers, which contains practically no free mineral, is then reground. Chilean mills have been used for this purpose, but the large increase in capacity of the mill had overtaxed them, and it was decided to test pebble mills for this work. Accordingly a Power & Mining Machinery Co.'s improved tube-mill, 7 ft. diameter by 10 ft. long, was installed for competitive test with the popular type of conical pebble mill, 8 ft. diameter with a 30-in. cylinder. Each mill was driven from a separate and independent motor, belted to the pinion shaft. The packet type of lining was used in the straight mill after the first test, and it was found that plain plate lining wore too fast. The conical mill was lined with El Oro lining in the cylindrical section, and 18 in. of the discharge cone, the remainder of the mill was lined with plate. Six-inch lifters were also used in the conical mill during the first test, but were removed at the suggestion of the builder's representative.

*Prepared by the chief engineer for Power & Mining Machinery Company.

The initial charge to each mill was No. 4 Danish pebbles and additional pebbles of the same size were fed, together with the feed during the test, as needed. Speed of the straight mill remained at 22 r.p.m. throughout the test. The conical mill was first run at 30 r.p.m., but this was later changed to 25 r.p.m. The axis of the straight mill remained horizontal throughout the test, while the conical mill was raised 1½ in. at the feed end following the completion of the first test, owing to excessive flattening of the pebbles. The ground product discharged from these mills was elevated by bucket elevators and discharged to the Richards-Janney classifiers already mentioned, and it will thus be seen that each mill formed part of a closed circuit and that any oversize was returned. Owing to the inability of one section of the concentrator to furnish enough feed for both mills, they were installed in separate sections, and it was not practicable to split the feed going to the mills. This did not permit of ideal testing conditions, but every effort was made to keep each mill running on the same class of feed. The object in view was to grind this 10 to 30-mesh material so that the largest percentage would pass a 40-mesh screen, yet at the same time produce the least possible amount of minus 200 mesh material.

It seems from the result of this test that not the shape, but the dimensions of the tube-mill are the factors to be taken into consideration in figuring capacity, the class of product to be produced, and efficiency. It is true that an all-slime product can be secured from a tube-mill, but it is also equally true that a granular product will be the result if the mill is built in the proper dimensions and operated under proper conditions. The tonnage treated, and percentage of solids in the feed also bear a strong relation to the product of the mill.

The results of these tests were such as to greatly strengthen the contention that no advantage had been gained by a departure from the cylindrical type of tube-mill, but the manufacturers of the mill prefer to delay publishing the figures obtained until they have had an opportunity to substantiate the same by further tests on other ores. Negotiations for such tests are now being carried on. The Power & Mining Machinery Co. will, however, furnish copies of these figures to anyone interested.

Commercial Paragraphs

THE TERRY STEAM TURBINE Co. of Hartford, Conn., is distributing a bulletin, No. 17, describing the return flow turbine made by that Company.

YUBA CONSTRUCTION Co. has issued a special bulletin, Model D, descriptive of irrigation pumps, a type suitable for any situation when the volume is large and the head low.

THE LUFKIN RULE Co. is now furnishing steel case liners and leather cases with push-button opener, with its general line of steel tapes, without extra charge. 'Challenge' and 'Challenge Junior' steel tapes now have leather cases, steel lined throughout. This gives the case extra stability, also permits making it narrower than before by ¼ in. 'Rival' and 'Rival Junior' steel tapes have nickel-plated steel cases as before, but the edge or case band is knurled to afford a good firm hand-hold. The cases of all these tapes are now also equipped with a positive action, winding handle, opener.

WATER SANDS in gravel beds may be easily made available as sources of domestic or industrial supply by means of driven wells. Such sands usually afford exceptionally pure water and if the wells be properly put in, it is free from contamination. In making such a well a special screened point attached to suitable lengths of pipe, is actually driven through the overlying beds and into the water sand. For such use pipe must be especially well made. The NATIONAL TUBE Co. makes a 'National Reamed and Drifted Pipe' which is described in Bulletin 18A in which will also be found a complete account of the method of making such wells.

EDITORIAL

WHAT it will cost to mine coal in Alaska is a matter about which there has been much dispute. We are glad to present this week definite statements of what it has cost, written by Mr. W. R. Crane, who obtained his figures on the ground and who is thoroughly familiar with coal mining costs elsewhere.

UPROOTING a batholith might well be considered an attempt to get to the bottom of things. Mr. A. C. Lawson has just published a suggestive paper in which he shows that, so far as published evidence goes, there are no adequate grounds for considering the granite at Butte to be batholithic. If, as he thinks, it represents a laccolith, opinions regarding the genesis of the ores will need further revision.

IN New Zealand, according to a decision recently handed down by the chief justice, Sir Robert Stout, "it is not lawful for the defendant union to apply any of its funds for the purpose of assisting unions while the members of those unions are engaged in a strike. The union cannot make levies on its members for that purpose." Evidently, so far as legal machinery can be used to that purpose, strikes are to be blotted out in this, universally considered to be the most progressive of the Dominions.

MEETINGS of the engineering societies are now in season. The American Institute of Mining Engineers assembled at New York this week. We print on another page the program of the technical sessions which were so crowded this year that the meetings were held in sections. This is a healthy sign of the new interest in the Institute as a technical society which is now so apparent. Supplementing the regular sessions, semi-technical ones were scheduled for Tuesday and Thursday evenings and at 4:30 on Wednesday afternoon where Messrs. H. W. DuBois, I. N. Knapp, and Samuel A. Tayler gave illustrated lectures on various phases of mining. The Canadian Mining Institute is to meet at Montreal March 4, 5, and 6, and any engineer who can arrange to be present is sure to be well paid for his time. Thursday morning, March 5, an excursion will be made through the Mount Royal tunnel, which was recently holed through. In many particulars this tunnel and the work done while driving it are of unusual interest. The Mining and Metallurgical Society will meet at dinner in New York on

the evening of March 9 to present its medal to Mr. and Mrs. H. C. Hoover. This is to be a ladies' night, and the Society, already famous for its dinners, will make especial efforts to honor the occasion.

TELEGRAPHIC advices from New York indicate that the sessions of the American Institute of Mining Engineers were well attended this week, though discussion was occasionally hampered by the absence of the author of the paper read. At the business meeting, Mr. B. B. Thayer was elected president, Mr. Sidney J. Jennings first and Messrs. H. C. Hoover and W. L. Saunders second vice presidents, with Messrs. G. C. Stone treasurer, Bradley Stoughton secretary, and R. W. Brock, C. W. Merrill, A. R. Ledoux, H. L. Smyth, and D. C. Jackling additional directors. It was announced that the land debt had been fully paid, and in every department of the work of the Institute the outgoing administration was able to report affairs in excellent condition.

PRACTICAL men as well as educators will rejoice in the consummation of negotiations for coöperation between Harvard University and the Massachusetts Institute of Technology in support of engineering education and research. The agreement just reached covers the fields of mechanical, electrical, civil, sanitary, and mining engineering, and metallurgy. The work in these departments is to be conducted in buildings belonging to the Institute to be erected on its new site at Cambridge, bordering Massachusetts Avenue and the Charles River Embankment, but both teaching and research work are to be supported by practically all the funds of both institutions available for such work. While it is impossible to syndicate brains, and independence is of first consideration in intellectual work, we believe that the plan here adopted will appeal to the good sense of the graduates of both great schools. It was shown by investigation of the Carnegie Foundation that educational institutions, judged by ordinary business standards, are most inefficiently run. There is endless and unnecessary duplication of plant and apparatus, much of which is idle 80 per cent of the time. No thoughtful man wants his *Alma Mater* to become a factory, but it is anomalous to lecture embryo engineers on efficiency of plant under conditions ordinarily obtaining at universities. Germany was characterized some years ago by Lord Palmerston as "a land of damned professors." Since that was said the professor both in Germany and the United States has demonstrated his practical value to the social organism to an extent then wholly unsuspected; but Germany, in the judgment of keen and sympathetic observers, is now over-educated, and America is moving in the same direction. There are too many schools and there is not enough research. More engineers are being graduated than can be absorbed by industry, and each year men trained in engineering take up the selling of life insurance or some similar unrelated

vocation. At the same time, we continue to grope in the dark as to many fundamental problems. Only the large and rich school can afford, under actual conditions, to support research. The combination of forces and funds by Harvard and 'Tech', as it is known by its graduates, affords an exceptional opportunity for investigative work along engineering lines.

Leaching Copper in Africa

The great amount of attention which is being directed in this country toward the possibilities of the application of leaching processes for the recovery of copper from its ores tends to make us overlook what is being done abroad. There also proposals once discarded are being brought forth and reëxamined to see whether they cannot be so modified as to be applicable to present conditions. Sometimes they have been found impracticable as at the B'wana M'Kubwa copper mine, in northern Rhodesia, where it was proposed to erect a Siemens-Halske plant to recover the copper in the tailing from wet concentration. Various difficulties developed, chief among which is the discovery that the ore reserve was neither so large nor of so high a grade as expected. At the mine of the Bechuanaland Copper Company, also in Rhodesia, it is likewise proposed to use the Siemens-Halske process on the recommendation of Messrs. Hooper, Speak & Company. The Siemens-Halske process consists essentially of leaching the roasted ore with ferric sulphate solution, producing ferrous sulphate and copper sulphate. The solution is drawn off and electrolyzed, precipitating the copper. Though apparently simple, almost unsurmountable major difficulties arise, not to mention a number of annoying minor ones. It seems impossible to discover a satisfactory substance from which to make the anode, and in addition the ferrous sulphate is oxidized to ferric at the anode and reduced to ferrous sulphate again at the cathode, thus consuming much electrical energy to no purpose. This can be in part prevented by the use of a porous diaphragm, but this increases the resistance of the cell, and it is also difficult to find a satisfactory substance to form the diaphragm. The most important experiments made with this process in this country were those made at the Ray mine by Mr. W. Y. Westervelt, of which an account was given in our January 3 issue. The process has also been tried in Spain and elsewhere without success, and the results attained in Africa will therefore be awaited with interest. The most recent information is that the use of the Siemens-Halske process has been given up at the B'wana M'Kubwa, and it is now proposed to use the MacKay process, which has also been suggested as a possibility for the solution of the difficult metallurgical problem at the Tanganyika. The MacKay process as originally devised consisted in the production of a FeCl_3 solution, leaching the ore with this, forming FeCl_2 and CuCl . This solution is run over scrap iron, precipitating copper and regenerating the FeCl_3 . During the

past year or two. Mr. Archibald Carmichael has devoted a large amount of experimental study to the development of this process, but no official statement has been given out regarding the process in its present form. Many difficulties have been encountered, but it seems to be generally agreed that a high rate of extraction can be maintained on ores that are suited to the process.

Alaska's Opportunity Arrives

At last the way to the development of Alaskan coalfields is opening. The first great need is transportation. A bill providing for a system of government owned railroads in Alaska has passed the Senate and is now before the House of Representatives at Washington. It is expected to become a law shortly, and without material changes in form. Following its enactment, a law providing for the leasing of the coal lands is on the Administration program, and a bill for such an act has already been introduced in both House and Senate. After years of stagnation and conversation, something is finally to be done.

The railroad bill is a good one in most particulars. Whatever differences of opinion as to government ownership of railroads may remain, the system affords the only way out as conditions now exist, and if the Government is to build railroads in Alaska or elsewhere we think that public opinion is unanimous to the effect that the organization and control of the work should be as much like that obtaining at Panama as possible. There, Colonel G. W. Goethals and his associates made a success because of the recognition of the fact that, if the Government is going into business, it must recognize business principles. In particular, authority must go with responsibility and a definite plan must be formulated in advance. In the new bill the whole authority and responsibility for building the proposed railroad lines is lodged in the President, and adequate funds are made available from the first. Plans can be made, and contracts can be let, with full assurance that the money will be forthcoming at the time and in the amounts needed. This will avoid the greatest source of loss and waste incurred in river and harbor work where an irregular and unsystematic method of appropriating has resulted in the minimum of efficiency in plant and organization. It is further provided that the Government may buy or lease existing lines, and we are glad to see that some return, at least, is to be made to the pioneer railroad builders of Alaska who have every justification for complaint at the change in the rules of the game that was made after their work began. We believe in the active development of the territory. We see no reason why another Scandinavia with its vigorous civilization may not be added to the world, and we consider it a proper public enterprise to open the way to such a development. There is just one feature of the new law that appeals to us as particularly bad; that is the provision that no engineer may

be appointed to a position on the work at a salary exceeding \$3000 without approval of the Senate. Possibly this is merely a childish attempt to 'save face' on the part of power loving senators who, having consented to a big program, are not quite able to do it wholly and generously. The limitation, however, smells strongly of hopes for political spoils. Nothing would more surely or completely disgust the American nation with the whole policy of government ownership than to have the taint of partisan politics over the system. That may be one way to defeat what many opponents find it inconvenient to fight openly. We trust that the House will strike out this clause.

Following the railroad bill is one providing a leasing system for the coalfields. We are already on record as favoring such a plan. There are many who honestly oppose it, but it is now generally conceded that such a system is inevitable, and we believe those now in opposition will ultimately find its disadvantages fewer and less important than they now fear. We are glad to note that an indeterminate period of lease is provided, as was urged by the Mining and Metallurgical Society. The proposed leases are to be for the whole of the coal in the ground, and the lessee continues in possession so long as he fulfills the stipulated conditions. Certain rights of revision at intervals of 20 years are reserved to the Secretary of the Interior, and this is as reasonable as the usual right to revise rentals in the case of ground leases in cities. The amount of royalty, above a minimum of two cents per ton, is fixed by the lessee through competitive bidding. A small but increasing acreage tax applies during the period that the land lies idle before operations begin, and all funds arising from these leases are to be applied to the development, improvement, and betterment of Alaska, including railroad building. All this is excellent. We like less the restriction on acreage, though an allowance of 2650 acres is more liberal than the old 640-acre limit of the general coal land law. The most important feature of the law to which we would take exception is that making stringent provision against any possible consolidation of claims. In our issues of September 11 and 30 of 1911, we gave in detail our reasons for holding that such restrictions are unnecessary and undesirable. It would probably be impossible, however, to obtain any legislation at this time which did not include some such provision, and it is better to have a way open than to wait indefinitely for the best way. The system proposed is workable. It has many good points, and we hope it will be promptly put in operation. Alaska has been too long neglected. If the new legislation does not bring immediately the full prosperity for which our friends in the Far North hope, it will at least start the current in the right direction, and we confidently anticipate a time when people will wonder as much at the delay in opening the country as we now do at the difficulties anticipated when it was first proposed to build railroad lines to the Pacific Coast.

Mining in the Belgian Congo in 1913

By SYDNEY H. BALL and MILLARD K. SHALER

In Belgian colonial circles the financial depression caused by the break in rubber prices has been partly offset by the progress made in mining in the Belgian Congo. Although the gross mineral production in 1913 was but some \$3,000,000, it was, nevertheless, more than double that of 1912. The increase was due to a larger production of copper in the Katanga region, and a fair increase in the gold output. The year was further marked as the first in which the colony produced diamonds on a commercial scale. The past year has seen, as forecasted as probable in this review last year,¹ a start toward a lowering of the draconian mining taxes. These taxes must be further reduced, however, and in other ways mining offered governmental support, if the industry is to flourish in the colony. It is hoped that the acute labor situation in the Katanga, in particular, will be relieved.

The Congo has the reputation of being a land of cheap labor, and so it is per man per day, although the item of labor is not low. To one traveling through the country the labor supply would appear relatively abundant in some regions, but the unwillingness of the untutored native to work, causes a greater or less shortage of labor throughout the colony. New railroads and additional river steamers are locally reducing the number of porters and canoemen, a gain, however, much more than counterbalanced by new or growing enterprises. In the Katanga, where the largest mining operations exist, the labor situation is acute, and the future expansion of the enterprise may be affected. The determination of the value of many mineral discoveries made in that region, as well as railroad construction, is retarded. At present some 31,000 blacks are employed by various industrial concerns in the colony; of these, 9000 are in the Katanga, about one-third the number in reality needed.

Katanga Region

The mining region of the Katanga is sparsely populated and food is scarce. The country to the north, which has or had a fair population, is ravaged by sleeping sickness. Men recruited in more equatorial portions of the Congo are unsatisfactory, as they stand the—for them—rigorous climate poorly; further, they are needed for private and public enterprises nearer home. The Congo itself, then, cannot supply the demand. To the south and east lies Rhodesia, with at least a fairly large population, and this British possession has in the past supplied, and is now supplying, a considerable portion of the labor for the Katanga activities. Rhodesia, however, has industries of her own, and in fact is now suffering a dearth of labor which in the future is sure to increase. Moreover, it

is possible that the Rhodesian government may at some future date prohibit the emigration of its natives to the Congo, as it temporarily did in 1910, the pretext at that time being the danger of spreading the sleeping sickness. Portuguese Africa supplies a few laborers, and although the South African mines draw, in part, their labor from these colonies, it is believed that a considerable labor force may be obtained from Nyassaland, Portuguese East Africa, and Angola. Whether Africa, however, can or cannot supply to the Congo an adequate labor supply, is a moot question. The Bourse du Travail du Katanga (Katanga Recruiting Agency), founded under royal patronage on September 12, 1910, was expected by some to solve the labor situation, but up to the present time it has been unable to meet the requirements of the different companies.

If African sources fail, there appears to be but one way in which the Katanga can rank as the copper-producing region its resources apparently warrant—namely, by the importation of Chinese labor. The Belgians are by no means novices in handling such labor, for it will be remembered that some of the more important Chinese railways have been built by Belgian engineers with Belgian capital. Further, in 1893, some Chinese labor was used in the construction of the Lower Congo railroad. A year ago an attempt was made to import Chinese to work the tin deposits of Kasonso (Katanga), but unexpected obstacles rendered this impracticable.

What are the difficulties in obtaining for the Katanga these patient, industrious, Asiatic laborers? It will certainly be expensive, for the importation and repatriation of each coolie in South Africa costs about \$85; the corresponding figure for the Lower Congo railroad laborers was \$160. Each Chinaman traveling by way of Beira, the most practical route to the Katanga at present, would presumably cost the companies \$100. The initial outlay, while great, would perhaps in the long run be found to be well expended. Possibly the Rhodesian government would not permit these laborers to pass through her borders. In South Africa there is a strong sentiment of 'South Africa for the whites,' and public opinion would be strong against the introduction of Asiatics, even into the Katanga. This difficulty could, however, probably be surmounted if the Belgian colonial government would assure the British authorities that the number to be imported was comparatively small, and that adequate measures would be taken to prevent the coolies filtering across the frontier into Rhodesia. Mine managers, however, feel that prior to the introduction of Chinese or other foreign labor, the colonial legislation which practically makes the 'boy' master of all situations, must be modified. The final solution of the

¹*Mining and Scientific Press*, April 19, 1913.

question, however, naturally depends on the adaptability of the coolie to the climate. The Katanga copper belt, situated some 11° from the equator and being almost a mile above sea-level, does not suffer from a particularly trying climate. The establishment of absolutely sanitary compounds and the recruiting of

themselves. Such taxation, however, is the very warp and woof of colonial administration. Theoretically, the Congo native now pays his taxes in money, to obtain which he must labor, but in reality the proportion of natives who pay their taxes is decreasing. Ready money being unnecessary, the natives are losing

TRANSPORTATION ROUTES AND MINING DISTRICTS IN THE CONGO.

particularly robust coolies, perhaps from South China, should, however, be factors of such importation.

Taxation

Some two years ago, when trading in the colony became general and the state no longer collected the taxes in rubber and other products, laws were passed which decreased the labor efficiency of the blacks. Ethically, neither England, Germany, the United States, nor any other power, has the right to tax natives who, if their wishes were consulted, would prefer to govern

the incentive to work, and those employed are less efficient through having no fear of losing their jobs. Laws recently passed and their interpretation have diminished the prestige of the whites to an alarming degree. Their exaggerated clemency means to the natives weakness on the part of the whites, and results in lack of discipline, even where the intent is to safeguard the natives' health. As an example, from December 1, 1912, to May 1, 1913, 595 natives broke their contracts and deserted, at Elisabethville alone. Of these natives, but 30 were condemned, and most of

these spent but seven days in—to them comfortable quarters, with labor to perform less onerous than that of the mine. Due to the shortage of labor, many ‘boys’ naturally desert, with the perhaps natural purpose of obtaining a bonus for re-engagement elsewhere. Legislation recently passed may in the end be beneficial, though, in addition to legislation, its enforcement is essential to cause the native to respect his contract.

Facilities are being, and should be, further extended to enforce the young native to school himself, not only in the common branches and trades, but also in the belief that manual labor is honorable and necessary. The native is by no means hopeless, but to become, in the European sense, a good citizen, he must be considerably transformed both intellectually and morally, and such transformation will require decades, if not centuries.

Since last reviewed,² transportation facilities have been extended and bettered. The railroad from Elisabethville to Kambove, a large copper mine some 100

Boma, Lower Congo (89 miles built, 71 miles operated).

The Congo river fleet has been added to during the past year, and harbor and river improvements continued. Both the colony and private interests have roads under construction. Wireless telegraphy advances, and not only have Elisabethville and Boma talked with one another, but it is stated that the latter town and Brussels have signaled one another.

The Union Minière du Haut Katanga, in which company, it will be remembered, the Tanganyika Concessions, Ltd., has considerable holdings (about 42%), satisfactorily operated its copper mines in 1913. The production for the year was almost three times that of 1912. Although for the time being the fuel and ore supply problem appears to be solved, very rapid expansion is, as noted above, temporarily blocked by the present labor shortage. In his annual report for 1913, Jean Jadot, general manager for the Union Minière, presented the following table:

| | No. days working... | Ore smelted, tons... | Content of ore, %... | Tons of ingot Cu produced | Copper in ingots, % | Tons of Cu matte... | Matte Cu, %..... | Production of tons Cu per working day |
|-----------------------------|---------------------|----------------------|----------------------|---------------------------------|---------------------|---------------------|------------------|---|
| 1911 | 88 | 10,300 | 12 to 13 | 786 | 90 | ... | .. | 11.3 |

miles distant, was completed on June 24, 1913, and a semi-weekly service established. Leaving the port of Cape Town Tuesday at 11 a. m., Kambove is reached at 7 o'clock the following Monday evening. Grading at both ends of the railroad from Kambove to Bukama, on the Congo river (190 miles), the last link in an all-rail and steamer route from Cape Town to the Atlantic ocean at Matadi, has been commenced. This road presumably will be finished in a couple of years.

The German Dar-el-Salaam-Lake Tanganyika railroad has just been finished, and the Belgian road from Kabalo on the Congo to Albertville on Lake Tanganyika was, on October 1, 1912, 45 miles from the lake. With the completion of the latter railroad, which should take place some time late in the spring of this year, there will exist an all-rail and steamer trans-African line from Dar-el-Salaam on the east to Matadi on the west coast. The distance is about 2980 miles, a little over one-half being by railroad. The Benguela railroad, traversing Portuguese West Africa and heading toward the Katanga copper field, has as its rail head Bihe, 323 miles from the Atlantic ocean. The Mayumbe railroad is slowly being extended north from

The total production for 1913 approached 7200 long tons of crude copper, with a copper equivalent of about the same number of short tons. In 1914 the production should be some 9000 or 12,000 short tons of copper. Analyses of shipments follow:

| | April 1913. | July 1913. |
|---------------|-------------|------------|
| | % | % |
| Copper | 94.15 | 93.85 |
| Cobalt | 2.80 | 3.25 |
| Iron | 0.92 | 1.80 |
| Sulphur | 1.20 | 0.80 |

The Star of the Congo mine, situated near the smelter, produced monthly in 1913 about 15,000 tons of ore, of which 7000 tons was sorted and in part stock-piled for possible future treatment. Two steam-shovels to strip the overburden will soon be in operation. Early in 1913 two small sizing and washing plants were installed at the mine, and a set of log washers to enrich the talcose ore was to have commenced operation about the first of the present year. Formerly all ore had been obtained from this one mine, but early in June 1913 the railroad reached Kambove, and since August the smelter charge has consisted of sorted ore from the Star of the Congo mine, screened ore from the Kambove mine, and briquetted ore from the Luushia

²“Transportation Facilities in Central Africa,” S. H. Ball and M. K. Shaler, *Mining and Scientific Press*, April 12, 1913.

mine. Kambove furnishes about 600 tons of ore per week. At present the ore is being extracted in an open cut and dropped to a haulage tunnel, but in 1914 steam-shovels and open-cut mining are to be introduced. The Luushia mine, situated on the Elisabethville-Kambove railroad, at a distance of 56 miles from the smelter, can furnish daily 100 tons of pulverulent ore. During the year development was done at the Luiswishi, Likasie, and Chituru mines. The Union Minière employs at present about 200 whites and over 2000 blacks.

There was installed at the smelter in August a 6-press briquetting plant with capacity of 250 tons per 20 hours. No binder is used. The briquetted ore, especially that of the Luushia mine, is said to be excellent for smelting. The necessity of more extensive concentrating plants is recognized, and the question is being studied.

Consumption of Coke

Up to the end of 1912 European coke only had been used, but at that time Wankie (Rhodesia) coke began to be employed, and in 1913 constituted the only fuel. At first the coal prior to coking was not washed, and the coke, being high in sulphur and ash, was of poor grade. A coal washery has since been established, and partly due to this the average fuel consumption per ton of copper has fallen as follows:

| | | Tons. |
|--|------|-------|
| European coke | 1911 | 3.44 |
| European coke | 1912 | 3.00 |
| Wankie coke, unwashed (first half-year)..... | 1913 | 3.44 |
| Wankie coke, washed (second half-year)..... | 1913 | 2.90 |

A contract has been made with the Wankie Colliery Co. for 1500 tons of coke per month. In addition, one set of 22 Coppée coke-ovens, with monthly capacity of from 1500 to 1750 tons, was completed at the smelter in December 1913, and a second similar unit will be ready early in 1914. These are to use Wankie coal, the gases being used to fire boilers.

The two water jackets have worked fairly continuously since April 1913, and it is hoped that in 1914 they will work even more satisfactorily. A third water jacket has been sent to Africa and when this is installed at least two can presumably be kept in continuous commission. Mr. Jadot reports that during the months when the two water jackets were working simultaneously, using coke from the washed Wankie coal and Kambove and Luishi ore, the cost on board train at the smelter was about 700 francs per ton (this figures to about 61¢. per pound). The freight to Antwerp is about 300 francs per long ton, the copper costing a little over 9¢. per pound at Antwerp. In 1912 the cost was about one cent per pound higher. In this figure neither general expenses nor marketing charges are included, and the average price of the copper produced during 1913 was somewhat above these figures, as the two furnaces were not running continuously. With a larger production, better ore dressing, and with coke made at the smelter, the cost should be somewhat further reduced.

In 1913 most of the copper was sold to the highest bidder in the Antwerp market, but a part of the product is said to have gone to Swansea, England. Cobalt, in addition to copper, is sometimes paid for. The production of 1914 has been contracted to the Frankfurt Metall-Gesellschaft, at prices varying with London quotations.

D. A. Lyons and M. R. Keeney, in the August 1913 *Bulletin* of the American Institute of Mining Engineers, pages 2134-5, give an interesting extract from an article by Stephan, who conducted at UGINE, France, experiments on the electrical smelting of the Katanga ores. Negotiations with the colonial government as to the formation of a subsidiary Belgian company to develop electric power in this part of the Katanga have been carried on, and it is possible, if financial conditions warrant, that such a company will be formed in 1914. It is of interest to note that the Belgian administration has had P. K. Horner, an American, as manager in Africa, and that recently A. E. Wheeler, the former superintendent of the Great Falls smelter, has been appointed consulting engineer.

Gold Mines and Production

The gold production increased satisfactorily in 1913, the output, if the state's forecast for the Kilo and Moto mines is correct, being some 1380 kilograms, valued at about \$828,000. In midsummer there were widespread reports of sensational gold discoveries in the Belgian Congo. These appear to have been without foundation. Fair alluvial ground has been discovered during the year at several places in the Uelle and in the Katanga, and some gold quartz in the Kilo region, but none of these are, as yet at least, known to be of much importance. Those at the head of Kibali river, southwest of Moto, appear most promising.

The four producing gold placers in the colony are situated in the northeastern part of the colony, a region of ancient rocks which have been deeply eroded. Beginning with January 1, 1914, the state will turn over to the Grand Lakes Railroad Co. the two larger placers of this region, Kilo and Moto. The profit beyond a certain amount, however, is to be divided between the colony and the railroad. In return for these and certain extensions to its prospecting rights, the Company relinquishes some 8,000,000 hectares of forest land. The Kilo placer is worked by primitive sluicing methods, although there is also a giant at work. About 30 whites and 2600 blacks are employed. The natives are paid a minimum wage of about 4¢. per day and are, in addition, given food, lodging, blankets, etc. The gold is said to cost about \$347.40 per kilogram, and to be worth about \$579 per kilogram (or \$18 per ounce), silver being the chief impurity. Some \$7,250,000 of gold-bearing gravel is supposed to be blocked out. At Moto, where sluicing began in 1911, seven white men and 1350 natives are employed. Gravels containing gold valued at \$500,000 have been proved to date.

In the parliamentary discussions preceding the transfer of these placers from the colony to the Grand

Lakes Railroad Co., the following figures were presented regarding the operating of the Kilo and Moto placers, under state regime:

| Year. | Cost of exploitation, francs | Sale of gold, francs. | Production. | | |
|------------|---------------------------------------|-----------------------|--|------------|------------|
| | | | Gold product of Kilo and Moto, kg. | Kilo | Moto |
| 1908 | 559,000 | 981,424.27 | 311 | 311 | ... |
| 1909 | 886,440 | 1,896,955.90 | 656 | 656 | ... |
| 1910 | 1,165,050 | 2,520,903.47 | 876 | 876 | ... |
| 1911 | 1,963,063 | 2,360,216.71 | 645 | 639 | 6 |
| 1912 | 2,052,262 | 2,834,551.83 | 984 | 740 | 244 |
| 1913 | 2,380,815* | 1,767,863.36† | 1360‡ | ... | ... |

*About.
†Incomplete.
‡Estimated.

Prior to 1908 the Kilo production was: 1905, 21 kg.; 1906, 212 kg.; 1907, 328 kilograms.

The Kanwa placer, owned by the Belgian-American company, Forestière et Minière du Congo, has added a small quota of gold, and the Babeyru placer has just started production.

Diamond Production Increases

To date diamonds have been found at the following places in the Belgian Congo: (1) in the gravels at many localities in the vast area lying in the triangle between the Kasai and Lovua rivers and the Angola (Portuguese West Africa) frontier; (2) as alluvial stones in the Mandoko zone in the extreme southwest part of the colony; (3) alluvial diamonds in Mutendola river, Katanga, a tributary of the Lualaba, and in that river itself above the rapids of Nzila; (4) in pipes in the Kundelungu mountains; and (5) at certainly three, and probably five, of the gold placers in the northeast part of the colony, as a by-product of gold placer mining. Of the latter, a few stones were obtained from the now abandoned state placer of Nebula-Bokwama, and several stones have been found at Kanwa and at least one at Babeyru, both placers being the property of the Belgian-American Société Internationale Forestière et Minière du Congo. The finding of several stones is also reported from the gold gravels of the Nizi river near Kilo, and of one at the Moto placer. Of these diamondiferous regions the Kasai and Kundelungu appear most promising. The Kasai is presumably by far the most important of these diamond regions, and its gravels, at least in part rich, are now being exploited on a small scale. Exploitation began the past summer, the product for the last half of the year being some 15,000 carats. The stones are of good water, but comparatively small, the grade being about that of the German Southwest African stones prior to the exploitation of the Pomono field.

*See S. H. Ball, 'Diamonds in the Belgian Congo,' *Eng. & Min. Jour.*, Feb. 3, 1913.

By a royal decree dated May 27, 1913, the Mandoko diamond zone was opened to general prospecting, as was a portion of the Kundelungu plateau region. In the latter region, however, the diamond concessions, covering some 250,000 hectares, or about 875 square miles, held by the Kundelungu company (the Katanga Special Committee and the Tanganyika Concessions, Ltd.), and by the Katanga Special Committee, were excepted. Within this area are the pipes now being investigated by these organizations. The pipes of the former company, which petrographically quite closely resemble those of South Africa, are eight in number (Talala, Louanza, Kogwama, Katipa, Maipaslu, Kambeli East, Kambeli West, and Shipuka), and the Katanga Special Committee owns four (Kataloi, Shilunga, Katwe, and Mafua, all on the Luizi river). The Kundelungu company began in the latter part of 1912 exploration of the Luanza pipe, and to the end of that year had found some 120 small stones. They averaged about one-sixth of a carat apiece, the largest being of about 3½ carats. At that time, about 4 whites and 60 to 70 blacks were employed. Since October 1912, from 250 to 380 cu. yd. of 'yellow ground' has been washed each month, containing a certain number of diamonds, from 30 to 40, according to some reports. A collection was exhibited in the Congo section at the Ghent Exposition the past year. In 1913 the same Company commenced preliminary work on the Msi-pashi pipe, which is connected with Elisabethville by motor route. Although the work at Luanza has not as yet shown it to be exploitable, the Company believes the work to be encouraging.

In the same region the Belgo-Katanga and the Industrielle et Minière du Katanga (recently amalgamated into the Société Belge Industrielle et Minière du Katanga) claim to have discovered 17 pipes of similar rock. These vary in size from 10 to 45 acres. The Company has taken as a prospecting concession one block of 200,000 hectares (772 square miles), and a number of smaller blocks. The 'ground' resembles closely the diamondiferous pipes of the Katanga Special Committee. In one area of about 10 acres, 80 bore-holes all struck 'blue ground' at about the same depth. It is stated that during the coming dry season (May-June 1914) testing will be begun on two or three of these pipes to determine whether or not they are diamondiferous.

Tin

But little advance was made in the past year in the Katanga tin region. At Muika, where both stream and lode tin occur, the Société de Recherches Minières du Bas Katanga has a small 5-stamp battery and concentrating plant. The cassiterite being rather coarse and the gangue light, milling is reported to be easy. The first concentrates reached Brussels in January 1913, and the monthly production in 1913 is reported to have been about ten tons of cassiterite. As a result of the excessive freight to Antwerp (over \$95 per ton of concentrate), and other high costs, the Company

has requested that the colony's allotment of profit be reduced, which presumably will be granted. A company is to be floated to exploit the 285 square miles of country at present held by the parent company. A plant to work the Union Minière du Haut Katanga tin deposits at Kasonso and Busanga was shipped from Europe in June. Up to early winter it had not as yet reached the mine.

Coal and Bituminous Shale

The coal reported to have been found last year on the Lukuga river near Lake Tanganyika and near the line of the railroad between Lake Tanganyika and the Congo, appears to cover a considerable area, the beds being traceable for some 12 miles. Some five slightly inclined beds occur at short vertical distances from one another. They vary in thickness from 2 to 6½ ft., and, taken together, are said to be some 16 ft. thick. The coal is sub-bituminous, hard and light, and some of it of brilliant lustre. It contains from 28 to 45% volatile matter, and 18 to 20% ash, and it has a calorific power of from 6500 to 7000 calories. For certain industrial purposes it will doubtless be a fair fuel. At present several white men and 200 negroes are prospecting the find, and if the royalty and taxes now claimed by the colonial government are reduced, a company will be formed to exploit it. In the vicinity of Ponthierville, on the Congo river, the Grand Lakes Railroad Co. estimates that there are available for quarrying 1,500,000 tons of bituminous schist, carrying from 60 to 100 litres of oil per ton.

The Congo copal, although in part fossil, does not perhaps strictly come within the province of this review. It is gathered from the surface by natives and by them sold to traders. The value of the product for 1910, 1911, and 1912 was, respectively, approximately \$250,000, \$635,000, and \$1,232,000.

General Prospecting and Mining Laws

Prospecting has been pushed throughout the colony during the past year although no startling discoveries have been reported. Up to June 30, 1913, in the Katanga, 369 locations had been made, of which 66 were for copper and the others for iron, manganese, gold, silver, platinum, tin, coal, bismuth, petroleum, diamonds, bituminous schist, cobalt, nickel, lead, and salt. During 1913 the Belgian-American company, Société Internationale Forestière et Minière du Congo, was given for 99 years the right to exploit its discoveries south of the fifth parallel south. The claims, chiefly for diamonds, gold, iron, and asphalt, cover about 4400 square miles. In 1912-13 the colonial government did a little drilling for salt near the salt springs in the Nyangwe region—upper Congo; no important discoveries resulted.

Several of the Katanga companies created in 1910 were in the past year in a position to begin exploitation, but they found the 33% of the gross production due by the colony, according to their charters, prohibitive. The matter has been taken up with the colonial

government, and a special committee has advised a considerable reduction in the taxes and royalties.

During the past year several of the Katanga prospecting companies have consolidated, and the stock of others has changed hands. In certain cases these companies, like the Grand Lakes railroad, have acquired an extension of their prospecting rights. During the latter part of the year some five companies asked for, and presumably will be given, prospecting rights south of the fifth parallel south, outside the blocks reserved by the Belgian-American company mentioned above. It is interesting to note that at least two of these are strong rubber companies, which, prior to the fall in the price of rubber, made large profits by trading in this region.

Mine Signal Codes

Following trips of the U. S. Bureau of Mines rescue car in the Lake Superior iron districts, some of the range associations of mining men are considering the changing of the signal code in general use to one which is simpler. The change is recommended by the officials of the mine rescue car on the ground that the simpler the code the safer and more effective it will be. The objection to changing is, of course, that accidents might result by confusing the new signals with the old; and, on account of the number of ignorant foreigners now working in the iron mines, it would take quite a long time before everyone entirely forgot the old signals and got accustomed to new ones. Under the old system generally in use, one bell is to stop hoisting or lowering, two bells means lower, and three bells means hoist. The new signals recommended would have one bell mean stop if in motion, hoist if at rest; two bells, lower; three bells would denote 'men on, run slow,' and the hoisting or lowering signal (one or two bells) would also be given.

The recommendations as given by a committee of the Gogebic Range Mining Association are as follows:

One bell: stop if in motion; hoist if at rest.

Two bells: lower.

Three bells: men on, run slow. Before men get on cage, ring three bells. The engineer replies with three bells if the return signal system is in use; if not, he replies by raising and lowering cage about six inches. When men are on cage, give hoisting or lowering signal (1 or 2 bells).

Nine bells: danger signal. Ring 9 bells, then station signal where danger exists, then repeat 9 bells. All hoisting must instantly cease, until verbal notice to engineer or by ringing of 15 bells releases the danger signal.

Fire signal: ring danger signal two or more times.

Station signals: shaft collar, 2-1 or 1 long.

First working level, 2-2 or 1 long and 1 short.

Second working level, 2-3 or 1 long and 2 short.

Third working level, 2-4 or 1 long and 3 short.

Fourth working level, 2-5 or 1 long and 4 short.

Fifth working level, 2-6 or 1 long and 5 short.

The committee recommended that in the interest of safety and efficiency, telephones should be installed at each working level.

Program of A. I. M. E. Meeting

New York, Tuesday, February 17, 1914

10 a.m.—Annual business meeting.

10:30 a.m.—‘Mining and Mining Methods in the Southeast Missouri Disseminated-Lead District,’ by H. A. Guess; ‘The Mill and Metallurgical Practice of the Nipissing Mining Co., Ltd., Cobalt, Ontario, Canada,’ by James Johnston; ‘The Disposition of Natural Resources,’ by George Otis Smith.

2 p.m.—‘Use of Electricity at the Penn and Republic Iron Mines, Mich.,’ by William Kelly and F. H. Armstrong; ‘The Application of Electric Motors to Shovels,’ by H. W. Rogers; ‘Electric Traction in Mines,’ by Charles LeGrand; ‘Safeguarding the Use of Electricity in Mines,’ by H. H. Clark; ‘The Safety of Underground Electrical Installations,’ by C. M. Means; ‘The Injection of Cement Grout into Water-Bearing Fissures,’ by Francis Donaldson; ‘Drilling Performances at the Kensico Dam, Catskill Aqueduct System, New York,’ by W. L. Saunders; ‘The Work of Crushing,’ by Arthur F. Taggart.

Wednesday, February 18

10 a.m.—‘Notes on the Plastic Deformation of Steel During Overstrain,’ by H. M. Howe and A. G. Levy; ‘Notes on Some Heating and Cooling Curves of Prof. Carpenter’s Electrolytic Iron,’ by Albert Sauveur; ‘The Influence on Quality of Cast Iron Exerted by Oxygen, Nitrogen, and Some Other Elements,’ by J. E. Johnson, Jr.; ‘Research with Regard to the Non-Magnetic and Magnetic Conditions of Manganese Steel,’ by B. Hopkinson and Sir Robert Hadfield; ‘Manganese Steel, with Especial Reference to the Relation of Physical Properties to Micro-Structure and Critical Ranges,’ by W. S. Potter; ‘The Heat Treatment of Steel Castings,’ by C. D. Young, O. D. A. Pease, and C. H. Strand; ‘Notes on an Iron-Ore Deposit near Hong-Kong, China,’ by C. M. Weld; ‘Why the Mining Laws Should be Revised,’ by Horace V. Winchell; ‘Comparison of Mining Conditions Today with those of 1872, in their Relation to Federal Mineral-Land Laws,’ by R. W. Raymond; ‘Objections to the Apex Law in Mining Practice,’ by C. F. Kelley; ‘Should the Apex Law be Now Repealed?’ by Charles H. Shamel; ‘The Apex Law in the Drumlummon Controversy,’ by Charles W. Goodale; ‘The Classification of Public Lands,’ by George Otis Smith.

2 p.m.—‘American Steel Rail Situation,’ by R. W. Hunt; ‘Manganese-Steel Rails,’ by Sir Robert Hadfield; ‘Notes on Blast-Furnace Operation with a Turbo Blower,’ by S. G. Valentine; ‘Data Pertaining to Gas Cleaning at the Duquesne Blast Furnaces,’ by A. N. Diehl; ‘Pig Steel from Ore in the Electric Furnace,’ by Robert M. Keeney; ‘Notes on the Utilization of Blast-Furnace and Coke-Oven Gas for Power Purposes,’ by Heinrich J. Freyn; ‘Notes on Conservation of Lake Superior Iron Ores,’ by Charles K. Leith;

‘The Need of Uniform Methods of Sampling Lake Superior Iron Ore,’ by C. B. Murray; ‘Sound Ingots,’ by Sir Robert Hadfield; ‘The Segregation and Classification of the Natural Resources of the Public Domain,’ by Frederick F. Sharpless; ‘The Initiation of Title to Mineral Lands,’ by Albert Burch; ‘Good Ideas in the Mining Laws of British Columbia and Mexico,’ by F. L. Sizer; ‘Provisions for Judicial Review of Land Office Decisions,’ by M. D. Leehey; ‘The Apex Law Illustrated by Decisions in the Coeur d’Alene,’ by F. T. Greene; ‘Uniform Mining Legislation in all States Based on Federal Acts,’ by C. L. Colburn; ‘Location of Mining Claims Upon Indian Reservations,’ by Will L. Clark; ‘What is Mineral Land,’ by Grafton Mason; ‘Mining Law Revision—How to Obtain It,’ by E. B. Kirby.

Thursday, February 19

10 a.m.—Discussion on the question: (1) To what depth below the surface do the standing groundwaters extend? Opened with a paper by Alfred C. Lane. (2) To what extent is chalcocite a primary, and to what extent a secondary, mineral in ore deposits? (3) To what extent are the contact zones, often called garnet zones, produced by intrusive rocks from limestone walls, due to recrystallization of matter original with the limestones; and to what extent are they and their associated ores due to contributions from intrusive rocks? Opened with papers by Waldemar Lindgren and C. K. Leith. ‘The Anticlinal Theory of Oil Accumulation,’ by H. A. Wheeler; ‘Scientific Installations for the Economical Burning of Liquid Fuel of Any Specific Gravity,’ by W. N. Best; ‘The Use of Petroleum in Dust Prevention and Road Preservation,’ by W. W. Page; ‘The Killing of the Burning Gas Well in the Caddo Oilfield, Louisiana,’ by C. D. Keen; ‘An Oil-Land Law,’ by George Otis Smith.

2 p.m.—‘The Equilibrium Diagram of the System $\text{CuS-Ni}_3\text{S}_2$,’ by Carl R. Hayward; ‘Cyanidation of Silver Sulphide at Ocampo, Mexico,’ by Robert Linton; ‘The Genesis of the Mercury Deposits of the Pacific Coast,’ by J. Allen Veatch; ‘Ore Dressing at the Morning Mill, Mullan, Idaho,’ by Rush J. White; ‘A Proposed New Converter, and the Application of the Bessemerizing Process to the Smelting of Ores,’ by Herbert Haas; ‘Milling and Hand Sorting of Lead Ore,’ by R. S. Handy; ‘Nickel Deposits in the Urals,’ by H. W. Turner; ‘The Burning of Coal Beds in Place,’ by Alexander Bowie; ‘The Use of Oxygen Helmets in Mine Fire,’ by E. P. Dudley; ‘Geology and Ore Deposits of the Bully Hill Mining District, California,’ by A. C. Boyle, Jr.; ‘Cementing Oil and Gas Wells,’ by I. N. Knapp; ‘The Age and Manner of Formation of Petroleum Deposits,’ by E. T. Dumble; ‘Geology and Technology of the California Oilfields,’ by Ralph Arnold and V. R. Garfias; ‘Water Intrusion and Methods of Prevention in California Oilfields,’ by Franklyn W. Oldman; ‘Chlorides in Oilfield Waters,’ by Chester W. Washburn.

Mining Methods in the Bering River Coalfield, Alaska

By W. R. CRANE

Work in the Bering River coalfield has, taken as a whole, proceeded little further than the location of claims. Of the five districts into which the field may be divided, namely, Carbon Mountain, Cunningham Ridge, Kushtaka and Carbon ridges, Bering Lake, and Lake Tokun, the largest amount of work has been done in the Kushtaka and Carbon ridges district. The Cunningham district probably stands second, while Bering Lake and Carbon Mountain occupy the third and fourth places, and the Lake Tokun district the last. From the standpoint of actual mining or extraction of coal, there is only one property in the region in which coal mining has been attempted, namely, the McDonald property, situated in the Bering Lake district. While considerable coal has been mined on various properties, it has practically all come from development work, such as the driving of drifts and tunnels.

Following the location of the outcrops of coal beds, development was begun. Camps were built at the most advantageous points on the creeks and as close to the work as possible in order to facilitate the handling of supplies and labor. The majority of the openings are adits which were driven into the coal beds from the outcrops. Occasionally an adit has been driven with the expectation of discovering a coal bed, the structure of the ground having indicated that it might be reached more expeditiously by an adit from the point chosen.

In the table below are given data regarding practically all drifts and adits at present in the Bering River field.

A number of the openings here listed are marked

'caved'; there were others in similar condition, but in such shape that no attempt was made to collect data regarding them. It is a fair and reasonably close estimate that not less than 4500 ft. of exploratory pas-

| No. | Location. | Tot. length including No. laterals, of lat- ft. erals. | Kind of opening. | Air connection. | Size, ft. | Remarks. |

FIG. 6. INTERIOR OF TUNNEL, KUSHTAKA LAKE.

FIG. 7. TUNNEL ENTRANCE AND FAN, M'DONALD MINE.

sages has been driven in this field.

It is but natural that horizontal openings should be employed in the development of the coal beds of this field, and, owing to difficulties of transportation, the openings have been made along the course of the streams. Practically no development has been attempted on the outcrops situated on the slopes and summits of the mountains.

Adits, drifts, and slopes will be the commonly employed openings for the mines, the working of the coal lying above and below the adit and drift levels being accomplished by winzes or slopes. When slopes are driven from the surface the usual method of driving headings will be followed. Vertical shafts might be employed to advantage in some instances, but it is probable that an attempt will be made to keep the openings of the mines at as low a level as possible and to work from below upward as far as may be found practicable. All of the advantages of working with horizontal openings can be secured as a result of the nature and topography of the country and should result in a material reduction in cost of producing coal. The development of coal beds of more or less uniform dip which extend over considerable areas presents no serious or extraordinary problems, except when such beds are variable in thickness or are cut and disturbed by faults. The development of coal beds occurring in basins of varying widths and dips and pitching at various angles is quite a different matter. In the case of the regularly dipping beds the main haulage and air-ways would be driven down or up the slope, depending upon whether the beds were inclined below or above the level of the openings, headings and air-ways being turned off the main passages at such angles as to maintain proper grades for handling the coal.

Arrangement of Development

In basins the regularity and systematic arrangement of the development work possible in regularly inclined beds is largely lacking, and the headings or gangways follow the sides of the basins, maintaining such grade as is found desirable for haulage and drainage. Pro-

vided there are no faults in the beds, or counter folding does not exist, a more or less definite and regular arrangement of workings may be had in coal beds of uniform inclination or in basins. However, as faults, folding, and counter folding are prevalent in this field they will have to be provided for in the scheme of development adopted. Careful and systematic prospecting will indicate the existence of such irregularities so that they can be anticipated. The development of parallel beds, which are frequently found in this field, will require careful and systematic work, although owing to the fact that in many cases the beds stand almost vertically the conditions of support will be much less difficult than would be the case were they more nearly horizontal.

Rate of Driving Adits

The rate of driving drifts and adits in the Bering River coalfield varies largely with the character of material encountered, and the position of the strata, that is, whether the openings are driven parallel with or normal to the strata. Work done on Trout and Clear creeks and the Kushtaka and Carbon ridges district gives an idea of the usual rate of advance. Two men being employed in each instance, the rate was as follows:

| Time, days. | Advance, feet. | Average per day, feet. |
|-------------|----------------|------------------------|
| 20 | 102 | 5.1 |
| 20 | 88 | 4.4 |
| 26 | 100 | 3.7 |
| 26 | 44 | 1.6 |
| 3 | 16 | 5.3 |
| 12 | 39 | 3.2 |
| 20 | 88 | 4.4 |

Average advance for 2 men per day, 3.9 or 4 ft. in 8 by 7 ft. drifts.

About half of this work was done in coal and half in rock, either alternating solid coal and solid rock or a combination of the two. The rate of advance was, of course, more rapid in coal than in rock, and therefore exceeded 4 ft. Owing to the broken condition of the coal little or no powder was required in breaking it and pick work was all that was necessary. The ad-

FIG. 8. TUNNEL AT KUSHTAKA LAKE.

FIG. 9. TUNNEL AT CARBON CREEK.

vance when working regularly averaged about 5 ft. per day. In rock work blasting was required, the holes being drilled by hand and the advance was about 3 ft. per day.

The steel used for drills was $\frac{7}{8}$ -in. with 1-in. cutting edge. Hercules, and Judson No. 2, 40% powder was used. Holes were placed in such manner as to secure the best results and not according to any definite arrangement. The holes varied in depth from 2 to $3\frac{1}{2}$ ft. The charge of powder employed varied from 1 to 2 sticks. The usual practice was to drill four holes to the round, although occasionally five and six were necessary. For a round of holes to make an advance of 3 ft. five holes were required, using $7\frac{1}{2}$ lb. of powder.

particularly true when wheelbarrows are employed, but also when cars are used, care being taken to keep the bottom of the passage on one side of the ties free from coal and dirt. This is not always the case, however, for in the adit driven near the camp on Kushtaka Lake (See Fig. 8) a large drainage ditch was maintained on one side of the bottom of the adit. (See Fig. 2.) No record of work done in this tunnel is available but it would not be difficult to estimate the additional cost.

The adit on Kushtaka Lake mentioned above is

The cost of driving in rock and coal is \$4.50 and

FIG. 1.

FIG. 2.

\$1.44, respectively. Should it be necessary to employ powder in working coal, an amount not exceeding two charges would be used which would average $1\frac{1}{2}$ lb. per hole, or 3 lb. per round. The cost per foot of advance would then be \$1.49. The timber for support of drifts and tunnels costs nothing except for labor of felling trees, cutting sets, and placing them. Two men can cut and place three mine sets, together with lagging, in a day. The cost would then be \$8 per day, or \$2.66 per set. The sets are placed 5 ft. centre to centre and give support to 15 ft. of drift, at a cost of 53c. per ft. The cost of a passage excavated in rock and supported would be \$5.03; in coal, with and without the use of powder, \$1.97 and \$2.02 per foot of advance.

Usually no drainage ditches are made, which is

unusual in that there are four sections of different size in its 350 ft. of length. These are given below, the measurements given being from inside of sets:

| Section. | Length. ft. in. | Height. ft. in. | Width of | |
|-----------|--------------------|--------------------|----------|---------|
| | | | top. | bottom. |
| | | | ft. in. | ft. in. |
| 1st | 38 6 | 7 7 | 9 11 | 11 8 |
| 2nd | 156 6 | 7 7 | 7 0 | 9 0 |
| 3rd | 48 0 | 7 4 | 4 0 | 5 0 |
| 4th | 117 0 | 7 4 | 6 8 | 9 0 |

A sketch of the set used in the first section is shown in Fig. 3. This entire section was timbered with sets placed side by side, making a closed lining (see Fig. 6). In the other sections the sets were placed 4 ft. centre to centre. A standard set for drifts and tunnels is shown in Fig. 1.

The rock section of this tunnel will average about 8 ft. high by 12 ft. wide at the bottom. The timbers are hewn, which would increase the cost to practically that of sawn timber. There is only one other adit in the field that approaches the one mentioned above in size and cost. This is No. 18, as given in the list of adits and drifts. (See Fig. 9.) The two adits were driven by the same company, the Alaska Development Co., with holdings in the Kushtaka and Carbon ridges districts. Exploratory drifts have been driven in coal in a number of the mines in order to determine the thickness and extent of the coal beds in certain directions. These passages are usually as small as it is possible to conveniently work in, being 3 ft. wide and 6 ft. high.

FIG. 3.

As previously mentioned, the McDonald property on Bering Lake is the only one in the field in which sufficient development has been done to warrant calling it a mine. An airway has been driven in this mine paralleling the main drifts and haulage way, at the mouth of which a mine fan is installed. As the dip of coal bed in which the main drift is driven is rather high, over 50° , it is necessary to carry the workings up the dip. To accomplish this, raises were driven in the coal directly up the dip at intervals of about 100 ft. These raises are 50 ft. long, 6 ft. wide, and vary from 4 to 6 ft. in height being carried the full height of the coal bed. They are timbered with posts and caps placed 6 ft. centre to centre and are divided into two compartments by a centrally placed row of props. On the right side, looking up the raise, is a chute boarded up to a height of 2 ft. with 2-in. plank. The remainder of the passage is used as a manway. The chute is 2 ft. 6 in. wide, and the manway is 3 ft. 6 in. wide. (See Fig. 4 and 5.)

At the end of the raises chambers are turned off and driven at right angles with them and are consequently parallel with the main drift below. These chambers are in reality only drifts, being 6 to 7 ft. wide and carried the full height of the coal bed. The chambers are supported by posts and caps, as are the raises. A row of props is placed in the chamber about 2 ft. from the posts on the right side, looking toward the working

face. Canvas is tacked to this row of props to form a brattice in order that air may be conducted to the face of the chamber. The airway paralleling the main drift has a section of 7 by 7 ft. and is placed 12 ft. to the right, on the raise side. From the airway raises are also driven connecting with a passage joining the chambers, which is in reality a continuation of the chambers, but the space between them is walled up and reinforced by small sets consisting of posts and caps, forming a passage 2 ft. square. This passage acts as a regulator and controls the amount of air entering the chambers. The coal mined at the face of the chambers is carried to the top of the chutes in wheelbarrows and is drawn off below through an ordinary chute with a wooden gate. The object in driving the chambers horizontally is to facilitate handling in wheelbarrows and to reduce breakage which would result were the chutes closed and permitted to stand full of coal. As it is, a large percentage of the coal is almost too fine for use by the time it is delivered to the coast. The employment of battery breasts is therefore out of the question.

In moderately dipping coal beds of sufficient size to warrant extensive development, the chambers could readily be increased both in width and length. By opening parallel chambers or driving additional raises the use of brattices could be largely obviated, thus increasing the convenience and decreasing the cost of mining and coal. Cars could be substituted for the wheelbarrows, reducing cost and breakage.

Cost of Mining Coal

The cost of mining coal by the method described, which really consists in driving, would closely approximate the costs previously given for driving. The work of breaking down the coal is largely done by picks, although in order that the coal may be mined in as large pieces as possible it is preferable to employ a number of charges of powder for each advance. One man can readily advance a 6 by 6 ft. chamber 5 ft. in 8 hr. As no lagging is employed in the chambers one man can make and place one set and extend the brattice in half a day. The cost of support would then be equivalent to the cost of a half day's labor. The cost of breaking down coal in a chamber per day of 8 hr. would then be \$6.41, or \$1.28 per foot of advance.

Assuming that the specific gravity of the coal is 1.3, the 180 cu. ft. of coal in place would weigh 7.31 short tons, which is the amount of coal produced in advancing the 6 by 6 ft. chamber 5 ft. The cost would then be 87c. per ton. As only one vertical shaft has been sunk in the field, the Grade Trail shaft south of Lake Charlotte, and as that one is partly filled by a fall of earth from the outcrop, no data could be secured relative to the cost of the work.

There is little hope that the comparatively high cost of development and mining can be reduced so long as the present high price of supplies is maintained, which is due in large part to the high cost of transportation.

The building of one or more lines of railway into the field and the establishment of steamship communication with the large cities of the Pacific coast will bring the needed relief and place the field on a competitive basis with other operating fields.

A majority of the drifts and adits of the field have

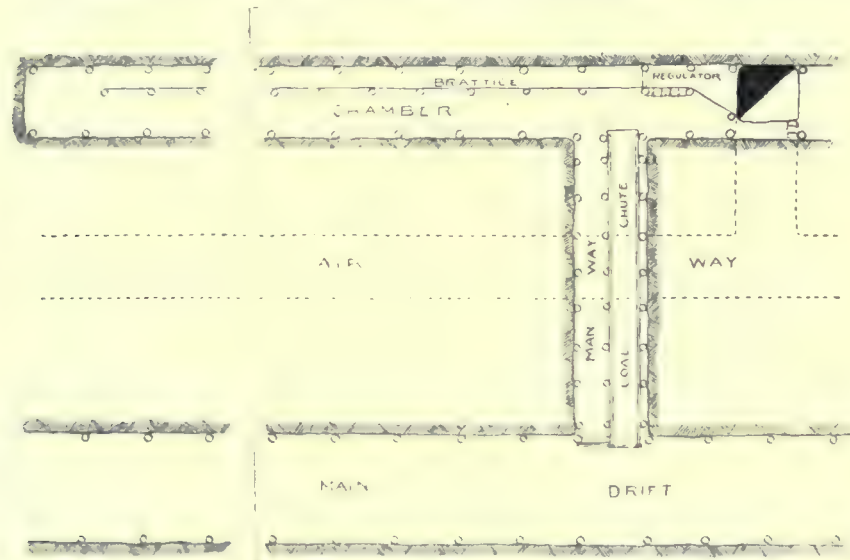

FIG. 4.

not attained sufficient lengths to make artificial ventilation necessary. Several of the openings have, however, been provided with means of insuring adequate ventilation. The means employed are: air shafts; raises connecting workings at different levels; air flues; and, in one case, an independent airway provided with a mine fan. An air flue is used in Trout Creek tunnel, and in Fig. 7 is shown the fan situated at the drift entrance to the McDonald mine. In the McDonald mine the fan can be employed either to force the air into or exhaust it from the airway, simply by reversing the direction of rotation. When used as a pressure fan the air currents first pass through the chambers, being discharged through the raises into the main drift; when employed as an exhaust fan, air entering the main drift is drawn through the raises and chambers and thence through the airway to the surface. A wooden box conductor is run along the top of the main drift and extends to within 20 ft. of the face, making connection with the airway by means of a diagonal offset at a point about midway of the drift. By this conductor the air at the face of the drift is kept fresh.

With respect to the dip of the coal beds there is nothing to prevent the application of the same methods of working that are in common use in the coal mines of other fields; and, owing to the fact that the coal beds of this region have the full range of inclinations from the horizontal to the vertical, an unlimited variety of methods could be employed each suited to a particular condition. There are, however, two conditions that will probably seriously interfere with and limit the application of any mining method to these coal beds, namely, the badly broken condition of the coal and poor top formations. The former will be of minor im-

portance provided the coals are used in making coke or for briquetting, but for steaming and other commercial purposes the prevention of undue breakage by handling will be a serious problem. Poor top formations will of necessity require narrow work or extensive and systematic support, in either case causing materially increased cost of production.

Owing to the position of the coal beds and the character of the country, the drainage of the mines is likely to prove a difficult task, particularly in those properties where inclined and vertical shafts and slopes are used. In the majority of the mines the openings, as previously pointed out, will be drifts and adits, in which case almost any quantity of water can be handled readily and at small expense. The drifts and adits at present driven discharge all water entering them, and that too without, except in one or two instances, drains being provided. Drains of ample section and special openings driven for drainage purposes alone would easily handle all the water that could reasonably be expected to enter the mines.

By adapting the coals of this region to the use to which they are best fitted by their chemical and physi-

FIG. 5.

cal properties there is little doubt but that they can be mined and marketed in competition with the coals of any other locality in North America.

Flotation of ores by the Minerals Separation process in 1913 was responsible for the treatment of approximately 3,000,000 tons of zinc, lead, and copper ores. During the current year the Company figures on its processes treating 4,000,000 tons.

Pis Pis Mining District

The concession originally granted James Deitrick in 1902 and subsequently acquired by the United States & Nicaragua Co. has since served to cast a cloud over mining titles in the Pis Pis district. The *American*, published at Bluefields, printed the map reproduced below, January 28, and in that connection stated that "it has been a question since the granting of this concession as to whether the mines in operation in the Pis

Great Falls, a water power that was almost conceded to it, is fully three miles to the eastward of the line.

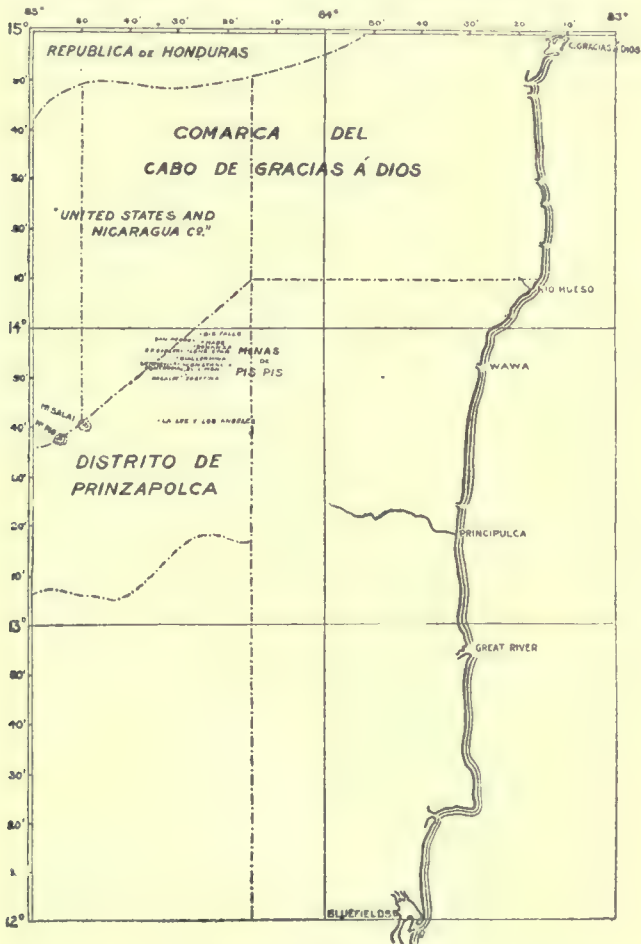

"While it is apparent that the concessionaires never had any intention of developing the territory, relying on the possibility that prospectors would locate claims which would accrue to them without the labor and expense attendant on intelligent prospecting, certain it is that they have suppressed the development of that immense territory, estimated at 7000 square miles, known to be the richest in all of Central America, for nine years, outside of creating apprehension on the part of legitimate miners in the Pis Pis district and preventing investment by capitalists who were anxious to safely establish themselves there."

Industrial Accidents Under Compensation

The Nevada Consolidated C. Co. and the Steptoe Valley S. & M. Co. have recently made public comparative figures of the number of industrial accidents in their plants before and after the Nevada industrial insurance law went into effect. The table below is summarized from these figures as published in the *White Pine News*. The first period was from January 1 to July 27, 1913, while the companies were carrying their own risk. The second, for which the figures are set in italics, was from July 28 to December 31, after the new law went into effect. Of the total number of accidents, 52.7% happened to the 'American' and 47.3% to the 'foreign' laborers. The second period showed a net decrease of 32% in time lost.

| Nevada Con. | Total | No. of | Total |
|-----------------|----------------|------------|-------------|
| Veteran mine: | shifts. | accidents. | disability. |
| American | 13,740 | 9 | 56 |
| | <i>6,120</i> | <i>4</i> | <i>30</i> |
| Foreign | 55,530 | 41 | 299 |
| | <i>34,110</i> | <i>12</i> | <i>210</i> |
| Steam-shovel: | | | |
| American | 53,340 | 36 | 703 |
| | <i>42,270</i> | <i>22</i> | <i>246</i> |

| | <i>363,420</i> | <i>132</i> | <i>1665</i> |

Large deposits of iron, copper, chrome, and other ores occur in the mountainous district of Asia Minor. Few mines have been developed, although a number of prospecting permits have been granted by the Turkish government. The Caramanian Iron Co. produces 20,000 tons of ore per year. Austrian and German mining engineers and promoters have recently visited this region with a view to purchasing some of the mines mentioned, but no definite transactions have been reported as yet.

MAP OF PIS PIS DISTRICT.

Pis district were included within the limits claimed by the concessionaires. The concession owners promptly laid claim to the district and the Government supported them by refusing to accept denouncements in the disputed territory. The mine-owners were very busy people during the first years, struggling with a high-grade ore and bad transportation; consequently nothing was done to settle the question nor to ascertain the exact position of the existing mines. The owners of the concession were not compelled by the Government to run their lines, and they have not yet done so. Recently the mine-owners arranged with William Pfaeffle, who is well known as an exact and careful engineer, to make the surveys necessary to determine the exact latitude and longitude of each of the mines, with the result of determining that not one of the properties in the Pis Pis district are within the boundary claimed by the United States & Nicaragua Co., and that even

Hydro-Electric Power in Chile and Peru

By LEWIS R. FREEMAN

*Fall, volume, and continuity of supply are the three prime essentials in the generation of electricity from water-power, and, except in the pampas country and the rainless district of northern Chile, these are to be found in almost every part of South America. From a mere physical standpoint, probably the finest opportunities for power development on the continent, if not in the world, are to be found on the eastern slopes of

eighth parallel, north of which to the Peruvian line are the rainless deserts of the nitrate provinces, south to Tierra del Fuego and the Strait of Magellan, there is not a city, village, or hamlet that can not be cheaply and efficiently served with electricity generated, in many instances, within 10 and in no case over 20 miles from its centre. And few, indeed, are the towns and cities of Chile which could not, between lighting, trolley

LAJA FALLS, CHILE.

the cordilleras of the Andes in Peru, Bolivia, and Ecuador, where the moisture-laden clouds from the Amazon valley dissolve into rain upon the cold slopes of the great mountain barrier. Here, lofty mountains and tropical rainfalls form a number of river systems which for waterfalls, cascades, and torrential rapids, are unrivaled in the world, save where the monsoon from the Indian ocean precipitates its moisture upon the southern slopes of the Himalayas. Unluckily, in this region there is not at present any market whatever for this power.

For easy and comparatively inexpensive hydro-electric development, Chile, with the possible exception of Switzerland and Kashmir, is the most favorably situated country in the world. From about the twenty-

lines, mines, sawmills, and general manufacturing, find the use of such power to its economic advantage. The narrow strip of Chile between the cordilleras and the coast is, for a considerable part of its length, as densely populated as Switzerland, and, with a people scarcely less industrious than the Swiss, there is no reason why the water-power possibilities of the Andes should not be turned to good account industrially here as in central Europe.

There are several hydro-electric installations, building or projected, in Chile at the present time, and though many of these are of greater magnitude, it is not likely that any of them will be begun at so fitting a time properly to impress the people with the possibilities of hydraulic development as happened in the instance of Valparaiso's first hydro-electric plant, when

*Abstract from the *Bulletin* of the Pan American Union.

there was a serious shortage of coal in Chile. Chile's finest power project is that of harnessing the magnificent falls of the Laja, sometimes called the Niagara of South America. The Laja is the main branch of the Rio Bio-Bio, which flows into the Pacific near Concepcion. The latter is the largest of the rivers of the southwest coast, and the Laja probably has a flow little less than that of the Hudson at Albany. The falls are over 100 ft. high, with the physical conformation of the banks of the river ideal for economic installation. Unluckily, this splendid fall hardly lies within practicable transmitting distance of the region where power is most needed, Santiago, Valparaiso, and the valley of the Aconcagua. Concepcion, Talchuan, Chillan, and the populous intervening country, with several hundred thousand inhabitants in all, will reap full benefits of Laja power, however, and several divisions of the government railway, with their branches, may be operated.

Opportunities for Development

Southern Chile, from the Bio-Bio to the Strait of Magellan, with its rolling hills, rich valleys, and heavy winter rainfall, has more water-power than it will know what to do with for some decades to come. Swift perennial streams flow from the mountains every few miles, and there is not a village in this part of the country that could not be served from two or three different sources. What is probably the finest opportunity for power development in this region occurs on the Rio Choshuenco, where that fine stream, in its 1200-ft. drop from Lake Perihueco to Lake Panguipulli, falls nearly 150 ft. at one point. Upward of 25,000 hp. could be developed there at a comparatively small cost, but the ideal installation would be an intake at Lake Perihueco with a power-house, 10 miles away and 1200 ft. below, on Lake Panguipulli. This would be an inexpensive piece of work; yet there are few other points in the world where 200,000 or 300,000 hp. could be developed at an equal cost. The fact that this power-site lies in the pass of San Martin, which, on account of its low altitude, will undoubtedly be chosen as the route of South America's first broad-gage transcontinental railway, makes it certain that a considerable market for power will be created for 200 miles east and west.

Chile's great power market lies in the cities of Santiago and Valparaiso and those of the populous Aconcagua valley, all of which are within practicable transmitting distance of each other and of a number of possible sites for development of hydraulic energy. The most comprehensive projects are those which plan to develop at a number of sites on the Colorado and Aconcagua rivers and transmit it to the various cities in the valley below. The Aconcagua is the fine stream which the railway follows down the Chilean side of the Uspallata pass, and the Colorado is its main branch. Both rise on the western watershed of the great Aconcagua, the highest peak in the Western Hemisphere, and are, therefore, drawing their flow from a storage unrivalled save by that of the Himalayas.

There are few sheer falls of great height on either river, but for 50 miles or more of their courses each of them is a torrent of cascades and rapids where a fall of 300 or 400 ft. may be obtained in a mile or two at almost any point. The minimum flow of these fine streams, if utilized only in such plants as are already projected, will furnish power for the most populous section of Chile for many years to come. There are a number of other good power sites within economical transmitting distance of Valparaiso and Santiago, but the Aconcagua-Colorado projects will probably fulfill the demands at the least cost. The hydro-electric installations which supply power in Peru are, perhaps, the most notable completed to date in South America. The largest of these is at Chosico, 25 miles from Lima, where a fall of 125 ft. has been secured in a short distance with a flow of five cubic metres per second. The current is transmitted to Lima at 33,500 volts. The Polovora plant in Lima utilizes a fall of about 80 feet. Another station at Chaora Sana, 3 miles below that of Chosico, utilizes the same waters, that of the Rio Reisano, to develop 6000 hp. By going farther afield, the power supply of the Lima district may be augmented greatly, and as plans for extending the interurban lines and electrifying the steam lines are being energetically carried out the local power demand is likely to prove very considerable.

At Charcano, 8 miles from Arequipa, 1000 hp. is developed at a station which receives its water through $1\frac{1}{4}$ miles of canal. The flow of water is 4 cubic metres per second, and the fall about 90 ft. Several other towns have modest hydraulic installations, as have also a number of mines, sugar plantations, etc. A hydro-electric station, which, with the Oroya railroad is the highest in the world, is at the Alpamina mine, at an altitude of over 16,000 ft. above sea-level. The electricity is generated direct at 3000 volts and transmitted about 5 miles. At this station, as well as those of the Cerro de Pasco mines, which lie at an altitude of over 13,000 ft., great precautions have to be taken to avoid the interference of static electricity, always a troublesome factor at great heights. In all, between 75,000 and 100,000 hp. has already been made available in Peru by hydro-electric installations.

The Power Market

A lack of demand, rather than of a potential supply, may be also ascribed as the reason for the fact that little has so far been done in hydraulic development in Bolivia, Ecuador, Colombia, Venezuela, and Paraguay. The three countries first named are especially well watered, while their physical conformation leaves little to be desired from the standpoint of the hydraulic engineer. Population and industrial development are conditions precedent to a demand for power at whatever cost, and until this demand is created hydraulic development will be confined to the vicinity of a few of the larger cities and the more progressive mining districts.

A Coeur D'Alene Electric Plant

By GILBERT B. ROSENBLATT

The electric equipment of the property of the National Copper Mining Co., 4 miles northeast of Mullan, in the Coeur d'Alene district of Idaho, constitutes one of the most interesting that has been made in that district for some time. Power will be purchased from the Washington Power Co. under a contract which makes it desirable for the mining company to maintain as high a power factor on its load as possible. The mining company has water rights from which approximately 600 hp. can be developed and it was determined to utilize this to supply part of the power requirements of the mine and mill, and at the same time to use these generating stations to improve the power factor as much as possible. Accordingly two hydro-electric plants will be built on Dead Mans creek situated so as to secure the maximum amount of power from the available water. In each plant there will be installed an impulse type water-wheel driving a 200-kw. 3-phase, 60-cycle generator. These plants will be connected to the load in parallel with the power supply of the Washington Water Power Co. No attempt will be made to regulate the load taken by these plants, and as a consequence the water-wheels will not be supplied with governors of the ordinary design. They will, however, be supplied with overspeed governors which will deflect the water-wheel nozzles in case, through any accident, the load on either or both of the plants is disconnected, which would tend to allow the water-wheel to race. When the machines are connected in parallel with the power company's lines, the frequency delivered will necessarily fix the speeds at which the generators can run and they will take as much of the mining company's load as the water running through the water-wheels will permit. They will, therefore, always be developing as much power as possible, yet their speed will be fixed and held constant by the frequency of the power company's supply lines. The fields of these generators will be so designed that, by adjusting their excitation properly, a high power factor on the entire load will be secured.

One of these hydro-electric plants will be designed for operation in the usual manner by an attendant in the station. The other plant is designed to run without attendance and the generator may be connected to or disconnected from the load from a distant point (the compressor station at the mine) by means of electrically operated switches. The governor on the water-wheel will be also controlled by the same mechanism which operates the switches and the plant will be stopped or started without anyone going near it. The installation at the mine will consist of approximately 300 hp. in induction motors, the largest being a 200-hp. Westinghouse motor driving an air-compressor.

The mill, which has been designed and is being built by the General Engineering Co. of Salt Lake, will be

driven by approximately 600 hp. of induction motors. Each department of the mill will be driven by a separate motor, the two largest individual machines being a 300-hp. motor on the Hardinge mill department, and 200-hp. for the dry-crushing department. All the motors will be equipped with suitable protective apparatus to cut them off from the supply lines in case of overload or in case of failure of power.

Electric haulage will be used underground to handle the ore, and the ore will be transported from the adit mouth to the mill over an electric railway, which is unique in some of its features. The run from the adit to the head of the mill is about 10,000 ft. and in this distance there is a drop of 450 ft. in elevation, necessitating a grade of $4\frac{1}{2}\%$ on the railroad. The railroad is built along the side of Dead Mans gulch and has a 24-in. gage and is laid with 30-lb. rails. The ore will be transported down this railway in trains of 8 to 12 cars, each car carrying 4 to 5 tons of ore. The equipment is designed to handle 500 tons in two shifts of 8 hours each. The average haul within the adit will be about 5000 ft. and the grade on this inside run will only be $1\frac{1}{2}\%$ per cent.

From this it will be seen that a comparatively light locomotive would handle all of the work inside of the adit but that a locomotive of about 8 tons in weight on drivers would be required for the work on the electric railway from adit mouth to the mill. It was, however, considered undesirable to have two different types of locomotives which could not be used interchangeably, and this was particularly so in view of contemplated extensions underground, which might require the service of an additional locomotive. Accordingly it was decided to standardize on a four-ton locomotive, which could be used independently underground, but which could be consolidated into an 8-ton tandem unit for haulage over the electric railway. This arrangement is of particular advantage in that it reduced the number of motormen required. Other advantages are that a double 4-ton tandem unit is easier on the rails than a single 8-ton unit would be, and also that with the gage in use adequate motor capacity of good design can be placed between the wheels of the locomotive. It is estimated that the tonnage handled can be doubled by adding another 4-ton locomotive at a later date, and arranging motors so that the two locomotives used underground can be used alternatively as the following unit of a tandem couple with a third locomotive operated only on the outside haul.

It was originally intended to construct a gravity tram to take care of the transportation of the ore from the adit to the mill, but a careful engineering investigation proved that an electric railway would handle the ore considerably cheaper, even on the steep grade involved. In fact a careful analysis which was made before a decision was reached indicated that the saving of the electric railway over the tramway would amount to several cents per ton handled. The installation cost of the railway is a little less than the esti-

mated installation cost of an aerial tramway. The saving in operating cost is effected by obviating the necessity of handling the ore at the adit mouth, and by reduced labor charges at the mill. With the present installation, the trips will be made up at the ore-chutes in the mine, and the complete train as made up at that point will proceed out through the adit over the railway to the storage bins at the mill, where the same crew, consisting of a motorman and a trip man, who came out with the train will see to the dumping of the ore.

All of the electrical equipment for this installation is being furnished by the Westinghouse Electric & Manufacturing Co. The electrical design for the mill equipment is in the hands of the General Engineering Co. and the electric haulage system is the work of F. Cushing Moore, chief engineer for the National Copper Mining Co., who worked in conjunction with the engineers of the Westinghouse company.

Counterbalancing Hoists

The Balliet system of hoisting in balance was described in our issue of December 13 but owing to restrictions incident to patent proceedings it was impossible at that time to give full details as to the method of adding the counter load. The figure herewith printed makes this matter clear. In addition to the ordinary counter-weight a series of chains are used as shown. These are of different lengths and hung from different points in the shaft so that it is possible by choice among them to balance the hoist at any level from which it is proposed to hoist. Details of operations at Tonopah, Nevada, are given below, the figures being taken from the annual report of the Buckeye Belmont Mines Co., for 1913:

| | Un-balanced. | Counter-balanced. |
|---|--------------|-------------------|
| Hoisting speed feet per minute..... | 700 | 700 |
| Depth of shaft (hoisting feet)..... | 1200 | 1200 |
| Weight of 1250 feet hoisting cable.... | 1160 | 1160 |
| Weight of empty skip..... | 1600 | 1600 |
| Net load of ore or rock hoisted..... | 1500 | 3000 |
| Weight of counterbalance cable..... | | 744 |
| Weight of cast iron counterbalance.... | | 500 |
| Continual balance weight (chain).... | | 1768 |
| Deadweight (skip down plus hoist cable) | 2760 | 1236 |
| Gross load, 1500 lb. rock to hoist (lb.).. | 4260 | 4236* |
| Computed power hoisting deadweight (hp.) | 59 | 27 |
| Actual peak or starting torque (hp.).. | 211 | 160 |
| Computed hp. ignoring friction for gross load | 90 | 90 |
| Computed hp. for 1500-lb. net load... | 31.7 | 63.6* |
| Power actually used (meter reading) hp. | 161 | 120 |
| Percentage of Power Used— | Per Cent. | Per Cent. |
| Computed to handle deadweight..... | 37 | 24 |
| Net load 1500 lb..... | 20 | 53* |
| Balance 71 hp. charged to friction... | 43 | 23† |
| Total per cent..... | 100 | 100 |

*With 3000 lb. †20 hp. charged friction.

Allowing two minutes time for starting, hoisting, and stopping, at 4c. per kw. hour, and the cost of rock hoisted is 20c. per ton unbalanced, and 8c. per ton when hoisted in balance. The theoretical horse-power required to raise one ton 1200 ft. in two minutes would cost 4c. at the rate of 4c. per kw. hour. Therefore these figures show that unbalanced the efficiency is 20%, while with the counterbalance the efficiency is increased to 53%, or in other words two and one-half tons is hoisted for what one ton formerly cost. There are some slight variations in these figures, apparent inaccuracies, which were unavoidable for the reason that in figuring horse-power a known load is supposed to have been hoisted in order to compute theoretical horse-power, instead of average load of rock, and absolute accuracy would be essential in the weight of the cable and empty skip. A few feet in length of the cable makes a difference in the meter reading likewise a little dirt sticking in the empty skip would make a difference, while the load used in making the figures was the average hoisting load.

The Supreme Court of Ontario, on December 19, delivered a judgment of considerable importance to mining prospectors. This was in the suit of Perron v. Hurd. They were prospectors in the Kirkland Lake district. In measuring his claim, Perron staked a length of 22 in place of 20 chains, and Hurd's claim, adjoining, consequently overlapped it by two chains. Perron contended that he had complied with the requirements of the law, to the effect that the measurements were to be "as accurate as could reasonably be ascertained," urging that it was practically impossible to give exact measurements. The Court decided that all claims registered, to be valid, must be accurately measured, and that no prospector could claim anything more than 20 chains each way.

Copper Production of Japan in 1913

From the returns of important mines, it has been estimated that the total production of copper in Japan in 1913 would be approximately 72,000 tons, the most important mines having made the following outputs:

| | Tons. |
|--------------------|---------------|
| Ashio | 10,600 |
| Kosaka | 9,000 |
| Hidachi | 9,500 |
| Besshi | 8,500 |
| Other mines | 34,400 |
| Total | 72,000 |

The production of copper in 1903, ten years ago, was only 32,000 tons, and that in 1912 was 65,000. Thus the copper production of Japan has been steadily increasing, and probably will continue to do so.

The Ashio mine stands first in output, not only in Japan, but in the Far East. The recent improvements of the mines and the works, and the completion of a railroad to the mine have made possible a marked increase and great economy. The future of the property is bright. A fire visited the property late in December, resulting in about 80 houses being burned near the Tsudo adit. No damage to the mines themselves occurred. The production of copper from Besshi is expected to increase hereafter steadily and the mine has large reserves. The Kosaka and Hidachi mines stand high in total production, but partly because of the smelting of custom ores from several mines. The Ashio and Besshi are the producers of copper from their own ores.

For many years Japan was an exporter of copper to the foreign countries, but this condition is now changing. The rapid development of wire making and manufacturing of electrical machinery is making Japan a user of copper as well as a producer. The amount of copper consumed at home in 1913 has been estimated at 35,500 tons; that is, about one-half the amount of the whole production. Estimates of this consumption are as follows:

| | Tons. | Per cent. |
|-------------------------------|--------|-----------|
| Copper wire | 14,500 | 40.8 |
| Copper articles | 2,500 | 7.1 |
| Brass making | 18,000 | 50.7 |
| Naval and army purposes | 500 | 1.4 |

The exports of copper for the 10 months ending with October were as follows:

| | Tons. |
|--------------------|---------------|
| China | 10,300 |
| England | 6,360 |
| France | 4,650 |
| Hongkong | 3,900 |
| India | 1,500 |
| Germany | 1,200 |
| Others | 5,290 |
| Total | 33,200 |

In the last two months the exports to China amounted to about 2000 tons, and to other countries about 1300 tons. The total may have reached about 36,500 tons.

Rulings of the California Accident Commission

The Commission holds that chauffeurs, private or otherwise, come under the compensation provisions of the act without any election on the part of the employer being necessary. It has also expressed itself as being of the opinion that the reasonable cost of necessary transportation immediately connected with the injury is a proper charge for medical treatment under the compensation act. It has ruled that members of voluntary fire departments, operating without remuneration, and public officers, who serve without remuneration, are entitled to medical and surgical benefits, but are not entitled to any other compensation benefits. In the case of farm employees, it expresses the opinion that work done on a farm by employees of the farmer for the maintenance and operation of such farm, is excluded from the compulsory provisions of the compensation law, but that such farm employees can proceed against their employers by means of a suit for damages, said suit being filed under the first two sections of the Roseberry act. The Commission has also stated that it will assume jurisdiction where employers residing in California and employees residing in California make a contract of hire in California, without reference where any accidental injury or death may take place. In each case of seasonal employees the Commission holds that it will seek to ascertain the average annual earnings by testimony showing the earnings throughout the year of the individual concerned. The Commission will be glad to receive and answer inquiries regarding interpretation of the law.

Cost of Hauling by Motor Truck

At one of the small lead mines in the Mississippi Valley a 3½-ton motor truck is used to haul concentrate from the mine to the railroad, a distance of two miles. On the return trip the truck hauls coal and supplies to the mine. The original dirt road was improved by adding crushed rock in places and a top dressing of 'chats' to make it suitable for hauling by motor trucks. The Company has kept accurate records of the expense of operating the truck so that it is possible to calculate the exact cost per mile and per ton-mile. The labor employed consists of a driver, a helper, and three loaders. The truck usually makes from seven to nine round trips in a day, and hauls a load of 3½ tons of coal or concentrate.

The records for the month of September, 1913, show that the truck ran 888 miles, and transported 1095 tons. It used 301 gal. of gasoline and 36 gal. of oil. The cost of labor for the month was \$256.35, which includes the wages of the driver, helper, and loaders. The cost of repairs was \$9.58; tires, \$39.96; road work, \$63.44; and unloading coal, \$2.80. The total operating expense was \$442.59, and the cost per mile was 49.82c. The cost per ton was 40.4c., and per ton-mile 20.2 cents.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Solution Control in Cyanidation

The Editor:

Sir—The publication of my contribution on solution control has evidently displeased James S. Colbath, whose criticism appeared in the October 11 issue. In his reply, Mr. Colbath utters a protest against an article which contained a résumé of the details of zinc precipitation, a discussion and a new definition of available cyanide, the results of a large number of experiments and tests, results showing the effect of the addition of acid to a normal cyanide solution, the results of experimental work dealing with the question of acidity and regeneration, and extensive arguments and details of tests intended to prove the absence of regeneration with alkali in plant solution under normal conditions. Under examination the 'protest,' as such, turns out to be little more than an apparent objection to details of tests intended to prove the absence of a recognized method of direct testing for free cyanide. In support of his attitude on the question he neither mentions nor does he discuss the arguments and proofs I brought forward in support of my contention; neither does he adduce one single argument or proof in corroboration of his own impressions. His attitude is inexplicable. He has evidently not taken the trouble to read the article he attempts to criticise.

LEIBIG'S METHOD

Mr. Colbath makes a definite statement that: "Most working solutions permit of a single determination of free cyanide by direct titration with silver nitrate regardless of the alkalinity." I most emphatically disagree with him in the expression of a timeworn theory. My article contained much argument and the results of numerous tests disproving this; and Mr. Colbath is not likely to advance his position one iota by the mere statement, even though it be associated with a 'protest' against any effort to throw more light on the matter. In the presence of zinc compounds there is no definite end point to be observed and, even if the results were approximately reliable, this fact would make the method unsuitable for routine control in the plant. Clennell states:* "The method works admirably with pure cyanide solutions, but gives very uncertain and inaccurate results in presence of some of the impurities which are generally introduced during treatment of ores."

"The method," Mr. Colbath continues, "depends on the presence of zinc, which acts as an indicator, and

in addition the solution must be perfectly clear, as well as the flask in which the titration is made." The use of zinc as an indicator is, as far as I know, quite new. In what form and quantity is it used, and what compound of zinc and silver nitrate is responsible for the opalescent end-point mentioned? Or does Mr. Colbath refer to a zinc compound in the solution when he mentions zinc? In any case, further details would be of interest. As regards the precautions which are insisted upon against an attempt to titrate with a cloudy solution and an opaque flask, these are elementary.

After quoting the generally accepted theory as to regeneration with alkali, Mr. Colbath continues: "The above method * * * will indicate decrease of free cyanide during precipitation, in contradiction of Mr. Allens' experiences, but in accord with the principles of chemistry." My statements on the subject were accompanied by definite and carefully checked titration results and referred to the instance, as I stated at the time, where there was an excess of free cyanide and a moderate alkalinity in the incoming solution. With a high alkalinity the whole of the cyanide both as free and combined would be indicated in the result of a simple titration test, using potassium iodide as indicator; and there should be no difference between the free cyanide content at the head or tail of the box, as indicated by this method. The initial alkalinity, plus the alkalinity formed during precipitation, would regenerate free cyanide from the double cyanide, according to the theory subscribed to by Mr. Colbath. Upon what reaction or evidence does he base his insinuation that my experiences are against the principles of chemistry?

Mr. Colbath next deals with the chemistry of the cyanide process and tells us that: "* * * it is sufficiently well understood for its intelligent application, so that the well-informed operator can usually determine free cyanide with more certainly and almost as simply as one whom I knew to determine alkalinity by feeling with his fingers." I have only one remark to make to such an unscientific statement, and that is—*he may think he can.*

EFFECT OF ZINC IN SOLUTION

Mr. Colbath is inclined to believe that I overrate the evils of zinc in solution. He tells us that he has never thrown away a ton of solution in twelve years on account of fouling with zinc. This may mean that he has thrown it away to prevent fouling, which would have been a wise precaution. Or he may wish us to understand that he has never thrown away a ton of solution at all. If the latter is the impression he wishes to convey, then it is obvious that his residues during those twelve years have not contained a total of one pound of cyanide, so perfect has been the displacement of cyanide solution from residue. Such a contention is too great a tax on our powers of credulity.

As regards the immunity which Mr. Colbath has

*Chemistry of Cyanide Solutions, p. 7.

enjoyed from the effect of zinc in solution, I must refer him to the article which he criticises, but which he evidently has not read. I stated: "The loss of zinc from plant solution is a mystery which has yet to be solved. * * * Whatever the cause, it is evident that the automatic reduction of zinc content prevents the fouling of cyanide solutions in the great majority of cases." Mr. Colbath's experience, as well as my own under many other circumstances, may well be included under "the great majority of cases." I then continued: "Under other conditions, however, as in the present instance, the reaction stops at a certain point, after which active measures must be taken for the removal of an undesirable accumulation of zinc. The strength of the cyanide solution entering the zinc-boxes must often be increased in proportion to the amount of zinc in such solution; and an unnecessary consumption of both solvent and precipitant results from an endeavor to effect satisfactory precipitation from foul solution." In a criticism protesting against an article containing such direct statements as these, Mr. Colbath's advice that "such troubles are usually due to insufficient free cyanide" is offensively gratuitous.

GOLD VERSUS SILVER SOLUTIONS

Still another reason to account for Mr. Colbath's immunity from trouble in connection with the presence of zinc in plant solution may be found in the fact that his experience may refer to the cyanidation of silver ores. Again I must repeat myself: "Satisfactory precipitation, from an economic point of view, is more a question of ultimate value than actual metal content. The 'barren' solution after gold precipitation may contain a few grains per ton as compared to the corresponding 'barren' solution after silver precipitation which may contain as many pennyweights. Each may be referred to as the residue after satisfactory precipitation, but it is evident that the question of zinc content is more important in the case of the treatment of gold ores where a complete or nearly complete precipitation is essential, a small percentage of the metal representing a high money value." In other words, a solution which under other conditions may be considered hopelessly foul may still be productive of good results in the treatment of a silver ore. Foulness is a relative term and not a definite one, and the whole aspect of the case is governed by the value of the metal being recovered. Zinc was abandoned at Nipissing in favor of aluminum on evidence of the loss of solvent power in the solution due to the accumulation of precipitant compounds. We learn from E. M. Hamilton's article† that the ordinary solution after zinc precipitation carried 0.8 oz. silver per ton. This is an amount largely in excess of the quantity of metal usually found in the highest grade gold solutions *before precipitation*. The fact that the tailing solution has since been reduced to 0.05 oz. is one of the strongest reasons, in my opinion, why more attention should be drawn

to a method of precipitation which Mr. Hamilton has described and the extension of which he advocates in his usual lucid and scientific manner.

AMOUNT OF FREE CYANIDE

Mr. Colbath next refers to two remarks I made in connection with a statement of trouble with cyanide solution. The first was to the effect that routine titrations by the ordinary method had been made regularly and showed no material alteration in the composition of the solution. The second stated that an analysis of the solution revealed a high zinc and copper content. After a statement of these two facts, Mr. Colbath adds: "It is quite evident that free cyanide must have been very low." In fact, and for some time previous to the successful removal of the copper, the amount of free cyanide was so high that the copper accumulated in the solution to the detriment of gold precipitation; and cyanide 'drips' at the heads of the boxes were without good effect. The subsequent variations in free cyanide content in order to precipitate the copper, and finally to allow for the removal of the excess zinc, have been fully described, and indicate the method by which a return was made to normal cyanide consumption and satisfactory precipitation. Mr. Colbath, in his discussion of the matter, omits all reference to the elimination of the copper and refers to the success following the adding of excess cyanide to the solution.

In the next paragraph Mr. Colbath commits another error. "I cannot accept Mr. Allen's statement in regard to function of hydrogen in precipitation. The liberation of hydrogen is sometimes incidental and not the cause of precipitation." In no part of my article did I say that hydrogen could cause precipitation. I said that it was an essential element in the reaction, and I have no hesitation in reaffirming such a statement. Mr. Colbath's remark that hydrogen is sometimes incidental to precipitation is interesting, but will he enlighten us as to the reaction when it is not? The fact that precipitation may be good without visible liberation of hydrogen does not support his contention, since the correct amount of hydrogen may be absorbed as soon as formed.

Mr. Colbath concludes with the following significant remark: "It appears to me that the solutions in question were saturated with zinc *to the extent of having all the cyanide combined.* * * *" The italics are mine and serve to draw attention to the implication that cyaniding operations were being carried on with an ignorance of the elementary conceptions of the process. Such an insinuation is as ill-judged as the statement itself lacks verisimilitude. Assuming that it were possible to obtain, under ordinary working conditions, a solution saturated with zinc salts to the exclusion of all free cyanide, what is Mr. Colbath's remedy? The addition of more cyanide involving a further fouling of the solution, and an increased consumption of chemicals. Again assuming

†Eng. & Min. Jour., May 10, 1913.

an ordinary alkaline working solution in such a condition, how does Mr. Colbath propose to test for cyanide content? By the adoption of a method which assumes the regeneration of free cyanide by the combination of zinc salts and alkali; and where the result would indicate a free cyanide content which, even according to Mr. Colbath, did not exist.

The inconsequent nature of the criticism is very manifest when Mr. Colbath's inference as to the saturated condition of the solution is compared with a previous statement suggesting that I had overrated the evils of zinc in solution. It is also obvious that he has no faith whatever in his own convictions on the question of regeneration of cyanide. When all the cyanide had been combined with zinc, why was not free cyanide regenerated by the alkali obviously present in the solution?

The ineptitude of Mr. Colbath's 'protest' is singularly well illustrated by the fact that his own professed views do not even persist to the length of his extraordinary letter; and he concludes with an inadvertent admission of the claims of my contention against alkaline regeneration.

A. W. ALLEN.

Lonely Mine, Rhodesia, November 21, 1913.

Balliet System of Counterbalancing

The Editor:

Sir—My attention has been drawn to the advertisements of the Balliet system of counterweighting hoists. This system is claimed to have originated at Tonopah, and has just been patented. Several mines have been willing to accept the claims for originality of the device and it is announced that they are 'licensed' to use it. It is my belief that the inventor is sincere in believing that his device is new in principle, but a comparison between the Balliet device and similar ones that I have seen is sufficient to show that it is not new and properly unpatentable.

There is the usual auxiliary drum over which the counterweight rope is hung. One end of the rope descends the main haulage or hoisting compartment, and this end is fastened to the skip, as is also the main hoisting rope. The other end of the counterweight rope enters the manway side over the auxiliary sheave and is fastened to the counterweight. "To the bottom of the counterweight is fastened a chain or flexible weight which is half the length of the shaft" (the quotation is from the Balliet literature) "this chain is called the counterweight tail line." Mr. Balliet fastens one end of the chain half way down the shaft to the timbers. Then follows a very excellent description of the method of working and the saving effected.

"This method of counterweighting is so simple that it is a wonder that it has never been thought of before." It has, and I have seen it; also, it is mentioned in principle in standard works, as in Ihlse's 'Manual of Mining' pages 148, 149, under the title 'Chain Counter Balance', also in that of the Despre method.

In fact with the Koepe, Whiting, and Camphausen systems it is difficult to put out anything that is not some modification. The Balliet safety chain also mentioned in the device I have never before seen, and to me, at least, is new. I am curious to hear from others on it. This safety chain is apart from what has been described above.

That Mr. Balliet may obtain a patent is by no means improbable. From times 'way back miners were used to set an auxiliary door in the head-frame and cut a notch in the centre of one end. Then on their bucket bottom they hung a short chain and on the end of the chain an iron ball. Up comes the bucket and passes the auxiliary door now standing vertical and above the collar. The door is let fall at a fixed angle, the bucket lowered and joggled until the iron ball caught in the notch, the main cable loosened, the bucket dumped over the inclined door used as a chute and shaft-closer. The bucket was again jerked up and free, the door raised by the engineer who dropped it, and the bucket descended into the shaft. Some man came here from the prairie, thought it rather clever, and got a patent on it!

Stirling v. Babcock & Willcox Boilers

The Editor:

Sir—There are some calculations, the value of whose results would not be one whit affected whether a 5-in. or a 5-mile slide rule were used in working them out. If the assumptions and premises are wrong, accuracy in the figures counts for naught. This is the trouble with Mr. Gulick's letter in your November 29 issue on waste heat boilers in reverberatory furnace flues. It seems to be "a very interesting example of" partly digested reading, and of taking up the rôle of critic without making sure of one's facts.

His "per horse-power" figures mean nothing, or rather they are quite misleading. The description of the boilers showed that they were all of the same nominal horse-power, namely, 400, so the evaporation duty of the two types under the given conditions of service were approximately as 1.37 to 1 per unit of heating surface for the B. & W. and Stirling types respectively. Moreover, the proper unit for a basis of comparison is not the horse-power, but the furnace. My notes were to show, and I still think do correctly show, which of two types of boiler attached to similar smelting furnaces saved most money per furnace under similar conditions, over similar periods.

S. SEVERIN SØRENSEN.

Braden Copper Co., Chile, January 5.

The Woolworth building is 750 ft. (51 stories) high, and weighs just 250,000 tons. It has 2000 offices, and F. W. Woolworth expects to realize in rentals \$2,500,000 per year. The total sales at the Woolworth '10-cent' stores throughout the United States amounted to \$66,000,000 in 1913.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Loss of power due to belt driving even under ideal conditions is appreciable, and may amount to as much as 5 per cent.

Combination charges of black powder and some high explosive in a hole to be blasted should not be permitted about mines.

A larger quantity of explosives is required in machine-drill stopes than in hand labor stopes to break a ton of ore on the Rand. This amounts to as much as 8 to 10c. per ton.

Ash from boilers fired by wood contains a high percentage of lime, and at the Messina copper mine, Transvaal, the boiler ash is being used as a flux in the furnaces for smelting ore.

Cost of shaft-sinking, station cutting, and cross-cutting at the Buckeye-Belmont mine, Tonopah, Nevada, in 1913 was \$37.68 to \$40.30, \$20.03, and \$10.09 to \$20.02 per foot respectively.

Fire clays may be tested by means of an ordinary blow pipe. Most varieties melt and ordinary impure clays fuse readily into a dark glass. Good fire clays do not fuse—though the smaller pieces may show a rounding of the edges.

Dredging ground near Dowden Falls, Jackson county, Oregon, includes a large apple orchard, which is to be dredged. The Washington and Oregon owners of the ground state that the entire orchard will be restored after being worked.

Flotation at Cobar, New South Wales, was found to be successful only on sulphide ores, and more particularly on sulphides exposing freshly broken and unoxidized surfaces. The presence of carbonates or sulphates was extremely obnoxious, decreasing the percentage of recovery, according to F. Danvers Power.

Stream line is a term originally used in hydraulics by ship builders and designers of turbines and signified the path of least resistance, which is followed by a water particle when it is forced or deflected by an object. A stream line automobile body is so shaped as to cause the least resistance of the air when a car travels at high speed.

The use of 'permissible explosives' is rapidly extending as the result of thorough investigations by the Bureau of Mines. Where the risk of gas or dust explosions in coal mines is a serious one, these explosives

are now used only. During 1912 more than 18,000,000 lb. of such material was used in the coal mines of the United States. Manufacturers report an increase of 50% in the sales of permissible explosives.

Bore-hole coefficients in drilling gravel deposits are often unreliable. In the report of Charles M. Rolker, on operations at the Lena Goldfields, Siberia, during the past year, he gives data regarding the unreliability of a bore-hole coefficient. On the Big Dogaldin claims, 25 drill-holes were put down. Of these, 11 holes gave a total average of 18 dwt. per cubic yard. If a 50% boring coefficient is assumed, this would indicate a value of 9.068 dwt. per cubic yard, a very satisfactory yield. These holes cover a stream length of about 3920 ft. It can hardly be said that these are sufficient drill-holes to give an average gold content and stream width for this distance, but Mr. Rolker based his Dogaldin estimate on them.

The specific gravity of a coin 900 fine in gold and 100 fine in copper is 17.29 when the specific gravity of gold is taken at 19.32 and copper at 8.92. Actual experiment on a \$20 gold piece gave the value 17.20 at 20°C., in terms of water at 20°C. as unity. If the weighings are reduced to vacuo, and the unit of specific gravity is changed to water at 4°C., the value becomes 17.15. This is the density at 20°C. in grains per cubic centimetre, according to S. W. Stratton of the Bureau of Standards at Washington, D. C. Gold coin is made up of 9 parts of gold and 1 part of copper, but not by volume. United States statutes, section 3514, relative to the weight and fineness of gold coins, is as follows: The standard for both gold and silver coins of the United States shall be such that of 1000 parts by weight 900 shall be pure metal and 100 of alloy. The alloy of silver coins shall be copper; but the alloy of gold coins shall be of copper or of copper and silver; but in no case shall the silver exceed one-tenth of the whole alloy.

Depression of the Atlantic coast region has long been believed to be in progress. The evidence that this region has sunk in comparatively recent geological time is unchallenged, but D. W. Johnson and others have been led to doubt the assumption that it is still sinking. To uphold the inferences drawn from a study of the geological phenomena, Mr. Johnson has recently brought forward the results of tidal observations and precise leveling in the vicinity of New York City. Tidal observations extending over a period of a quarter of a century show that the mean tide-level has not changed perceptibly in that time, and a series of precise level determinations in two areas show that the differences in elevation, as determined twenty five years ago and during the past years are less than the probable error of the measurements. There thus seems to be no evidence that the coast is either sinking as a whole, or that there exists any of the differential warping which might be expected to accompany regional subsidence.

Special Correspondence

DENVER, COLORADO

THE ROLLINSVILLE DISTRICT, ITS PRESENT CONDITION, EFFORTS MADE TO REVIVE IT, AND POSSIBILITIES.—THE GOLD DIRT, PERIGO, AND GOLDEN FLINT MINES.

The mining district of Rollinsville, in Gilpin county, originally known as the Perigo camp, is not dead, but in a sad state of hibernation. The mines, which once made the place a prosperous one, are the Gold Dirt, Perigo, Golden Flint, and several smaller properties such as the War Eagle, Blaine, California, and Mountain Chief. The camp languishes, not because all the orebodies have been discovered and mined, or that the ores are refractory and cannot be treated, but because the men who control the greater part of these mines, and who in the early days, by their enterprise, developed the camp, have grown rich and are simply sitting back, playing a waiting game. These men own over 100 patented lode claims, all the available placer ground in Gamble and Moon gulches, and the ground in South Boulder gulch from a mile above Rollinsville to Pactolis, besides other property termed ranch lands because of small alluvial deposits upon them. On all these lands the company pays taxes and has other expenditure. This sort of thing is enough to break the spirit of any camp. Up to the present time the waiting game has been played in one of three ways: to sell outright the developed workings for their full value; to work the developed properties by the leasing system, leaving the lessees to keep up the ground; or, when this ruinous policy could no longer be carried out, to amply capitalize the whole proposition, retain the bulk of the stock, and sell the remainder to raise enough money to put the properties back on a paying basis. The first two methods of procedure have proved more or less successful, the last a dismal failure.

To show the ruinous results of this procedure, it need only be stated that at the present time the old Gold Dirt mine stands idle and full of water, and its machinery rusting in spite of the fact that the property is equipped with a complete 50-ton modern milling plant and thousands of tons of profitable ore lies broken in the stopes. The Perigo mine is closed, although it produced \$7,000,000 above the adit-level, a distance of less than 700 ft. According to the report of Mr. Snyder, of the Colorado School of Mines, made since the workings were closed down, there is still \$600,000 net to be recovered from the old stopes. Because these workings make considerable water, no attempt has been made to mine below the adit-level.

The value of these properties now being withheld from production is well shown by the fact that the Golden Flint mine, considered one of the smaller properties, has, within one year of the time of its sale to outside people, been developed into one of the best mines of the district. Under the able management of James Elspass, of Denver, sufficient ore has been developed to warrant the erection of a modern 100-ton milling plant, now completed.

The final effort to put the old properties on a productive basis was made when a development company known as the Bellevue company was organized, Charles Knight, of the Rexall company of Leadville, undertaking the promotion of the deal. The plan was to develop the placer ground first; but the ultimate aim was to develop the whole of this large property. All parties to the contract seem to have acted in good faith. The investment was an attractive one, and shares should have sold well, and the final result undoubtedly would have been beneficial to shareholders and district alike. But an unfortunate quarrel between the owners and the promoters disrupted the whole affair, threw the properties into

the hands of a receiver, to be finally bought back by the original owners at a sheriff's sale last fall. It is needless to say that the camp has lost faith in these old timers, who should be the chief developers, and feel that the only hope for existence lies in the newer properties, and this hope is surely not without foundation. The Golden Flint, if its present efficient management continues, is bound to prove satisfactory. The Smuggler, the only other producing mine in the district, is just now recovering from two years of litigation. This was the result of a prospector adjoining deciding he had the apex of the Golden Flint lode. This mine will also make good, not only because there is ore in it, but because in George Ashmore, the superintendent and one-third owner, the company has a man who has great faith in the mine. The Smuggler is equipped with a 10-stamp, amalgamating and concentrating plant, simple in construction and operation, but makes a fair recovery—just the sort of mill one usually finds at the smaller paying mines in the Gilpin district. Besides these two mines, there are a number of prospects upon which considerable work has been done, and which will probably be good producers in the

THE PERIGO MILL.

future. The best ones are the Sea Bird, Siren, Diamond Bill, and Gold Queen, and also a number of smaller properties.

Some years ago there was begun in South Boulder gulch, about two miles above Rollinsville, an enterprise, which, had it been completed, would have made the camp one of the good ones of Colorado. The company was known as the Golden Sun company, and its idea was to drive a cross-cut adit, south about 20° east, to intersect all the main veins of the district. The ultimate aim was the Perigo vein, which, it was claimed, would be cut at a vertical depth of 700 ft. The other good veins would have been cut at depths ranging from 300 to 1000 ft., which is sufficient depth for all practical purposes at the present time. This adit would have afforded drainage for the various mines, a tramway to the Moffat road, while South Boulder creek would supply sufficient water for milling purposes. The trouble was that when the adit had reached a distance of 2465 ft., the promoters decided that a 50-ton modern mill was necessary. All efforts to resuscitate have proved futile. This is the situation in north Gilpin county at the present time, but there surely is a better day coming, as there are good veins and excellent ore all along the north and eastern slopes of Jumbo and Tip Top mountains and the ranges branching from them. When the Moffat road was built through this part of the country an immediate revival of mining was anticipated, but for reasons given above results have so far been discouraging.

PLATTEVILLE, WISCONSIN

OPERATIONS IN THE ZINC-LEAD DISTRICTS IN JANUARY.—WORK SUSPENDED AT MANY MINES.—DISTRICT OUTPUTS AND NEW WORK.

The month of January, 1914, in the Wisconsin zinc-lead field, was filled with incongruities. Not so many years ago operators stated that zinc ore must be on a basis of at least \$40 per ton, assay of 60% zinc, in order to make a profit. Spelter remained in advance of \$5 in January on East St. Louis quotations, closing the month at \$5.20 per cwt. Spelter ore ranged during the month from \$39 to \$41 per ton, basis, and yet the field witnessed a period of depression almost bordering on panic. Several of the best producers suspended operations indefinitely, while nearly every camp in the field witnessed large cuts in the wages of miners, breast and machine men, which resulted in many men leaving. On top of all this, however, it was seen after the reports for the month were well in hand, that January would be an exceptionally strong month from the standpoint of production. Ore buyers showed no strong desires to get into the field and bid. Two modern mining equipments in process of construction were shut down, and the men at this work dismissed. Separating plants at three different points kept going without time restriction, and made a fair turn-in of high-grade ore, one plant obtaining premium prices. Lead ore was in better demand, but there seems to be a concerted plan to hold this grade of ore until prices are better, and shipments were light. Production was fair, while the output of iron pyrite fell under the usual output. 'Dry-bone' producers in the northern camps were actively engaged all the month, but no market was afforded this grade of material, and several hundred tons of ore, ready for delivery, was carried over.

On the whole, the month compares favorably with the output for the summer months of 1913. Prospecting was continued vigorously at one or two points in the field, with excellent results. Leading mine managers declare that advances will be made in the price of ore, but that high prices are out of the question for this year.

Production by districts for January is shown in the following table, the separator product being included.

| Camps. | Zinc, pounds. | Lead, pounds. | Sulphur, pounds. |
|---------------------|------------------|------------------|---------------------|
| Benton | 5,210,000 | | 3,352,800 |
| Hazel Green | 3,430,000 | 126,000 | |
| Galena | 2,730,000 | | |
| Linden | 2,370,000 | 231,440 | 598,890 |
| Livingston | 2,356,000 | | |
| Cuba | 2,102,000 | | 687,320 |
| Platteville | 1,718,000 | | |
| Harker | 1,542,000 | | |
| Shullsburg | 1,014,000 | | |
| Highland | 768,000 | | |
| Montfort | 224,000 | 66,000 | |
| Mineral Point | 48,000 | | |
| Totals | 22,612,000 | 432,440 | 4,639,010 |

The bulk of the shipments from Benton came from the Frontier, Fox, Fields, Ewing, and Martin; Hazel Green, the Kennedy and Cleveland; Galena, the Black-Jack, Vinegar Hills, and Federal; Linden, the Ross, Glanville, Optimo, and Saxe-Pollard; Livingston, the Grunow, Peacock, Peni, Lucky Six, Coker, Ellsworth, and Rundell; Cuba, the Masbruch mine and National Separating Co.; Platteville, the East End, Enterprise, and Empire roasters; Harker, the Miffin; Shullsburg, the Winskill property only; Highland, the New Jersey Zinc Co. only; Montfort, the O. P. David mine; and Mineral Point, from small local producers.

Briefly stated, the more important happenings for the month are as follows: Local producers in the Highland dis-

trict were left out by ore buyers, and no deliveries of ore were made, 1000 tons of mine product being carried over. Linden showed new ore discoveries in Optimo mine No. 1, and a heavy production from No. 2. The Miffin district returned two producers, after an idleness of months. The Peacock Mining Co. was held liable for injuries to one Dolphin, a miner, by the higher court and judgment awarded for \$11,000. The Grunow, Shamrock, and Biddick mines suspended operations indefinitely. Platteville experienced an off month. The East End mine, the leading producer, was down for two weeks. Enterprise Mining Co. operated in the top flats with fair results. The Wilson mine at Potosi remained shut down. The Klar-Piquette failed to resume operations. At Cuba, the National Separating Co., affiliated with the Vinegar Hill company, made a large turn-in of high-grade ore but no effort to increase capacity. The Roosevelt mine, idle for years, was again placed on a producing basis. The Masbruch mine shipped steadily. The Benton district made a good showing. The Martin mine resumed operations after remodeling jigs. Heavy pump equipment and 250-hp. electric motors was installed at the Bull Moose mine, and initial shipments of zinc ore made. Building operations on a new plant for the Iowa Mining Co., were halted. Mining operations on the North Blende were suspended, pending the installation of new high-pressure boilers. The San Souci Mining Co., operating a new plant, stored ore in bins. Drilling operations continued for the Wisconsin Zinc Co., on the Robbins and Champion with astonishingly good results. A new 250-ton power and milling plant will be provided without delay. The Minnie Mining Co.'s plant is being dismantled and removed. The Calvert Mining Co.'s plant has been dismantled and removed to the Galena district. Longhenry Bros. suspended mining operations. In the Hazel Green district the management of the Cleveland Mining Co. suspended building operations on two new mining plants, one on the new Lawrence mine and the other on the Scrabble Creek property. The North-western Zinc Co., one of the heaviest shippers of this district during 1913, suspended mining operations, placed a new superintendent in charge, and began prospect work with drills. The famous Vinegar Hill mine, producing steadily and in volume since 1905, began removing pillars, evidence that the end of the big ore runs had been reached. Prospect work with drills on the Unity for this Company proved successful. The Federal mine operated double shift most of the month, turning in four cars of concentrate weekly. The famous Black-Jack mine, the property of the New Jersey Zinc Co., was down part of the month while repairs were made to compressors. Shipments of ore are being made weekly. The Brown, Merry Widow, Betsy, Indianapolis, Ryan, Glen Ridge, and Pittsburgh mines were all idle during the month. Low prices of ore on the medium and inferior grades is given as the reason for the suspension of operations.

BOSTON

SHARE TRANSACTIONS. TONOPAH STOCKS IN BOSTON. TENNESSEE COPPER. RESERVE BANKS AND MINING STOCK. MOHAWK DIVIDEND PASSED. F. A. HEINZE LITIGATION. MAYFLOWER AND OLD COLONY MINES.

The Boston Stock Exchange has recently broadened in activity, getting back to approximately 50,000 shares per day, the largest volume since June, when dealings covered upward of 50,000 shares at times. The Curb on some days does over 20,000 shares, whereas a few weeks ago, when business was almost at a standstill, the day's volume often fell to 3000 or 4000 shares. The creation of an 'Admitted Department' on the Curb has served to help out the representation, as some of the industrial shares traded in on the New York Curb have had a little market here through being quoted and dealt in under this new head. Up until recently Tonopah stocks received but scant mention and even less attention in Boston,

joined, as it has been, to its copper idols. But last year the Curb governing board created the 'Admitted Department,' and under this head a number of Tonopah stocks have been quoted, and news is being freely printed about them. The time is coming when Tonopah will no longer be a closed book to Boston, and operations of Tonopah Belmont, Tonopah Mining, West End Consolidated, and others in that district will be read about as eagerly as some of those from Arizona, Butte, and the Lake.

Boston is taking considerable interest of late in Tennessee Copper Co.'s stock and believes it is being accumulated by inside interests. The Company's acid department is on a stable basis, and between the copper and acid the Company is expected to pay this year in dividends 10% net on the present selling price of the stock.

The President's trust message was well received by Boston stock market interests, who believe the Administration is making a strong effort to conciliate business interests and that it will be successful in doing so. Boston is now unanimous for a regional reserve bank, and it is understood that the city will get one without opposition. It is predicted that the placing of a bank here will bring the local coppers into more favor and result in a broader market. Perhaps there will be no better concrete evidence of credit expansion under the new currency law than will be provided in the case of mining stocks, which have until the last year or two been under the ban by the banks as to loans. With a regional reserve bank here, the banks of Boston will be tempted to loan more freely at the higher rates which mining securities offer, and send their commercial paper at a lower rate over to the regional reserve bank to be rediscounted. Senator Weeks, formerly a member of Hornblower & Weeks, has been very influential through the stand he has taken in crystallizing New England sentiment in behalf of the currency bill.

The well known porphyry copper banker, Charles Hayden, heads a group of Boston men interested in the building of the cup defender *Defiance*, which is now being built in Maine.

Strike conditions forced the Mohawk company to pass its semi-annual dividend, as did the Wolverine. These are what is known in Boston as the 'Stanton properties,' and in a preceding generation were looked upon as being soundly conducted. Extreme conservatism has always marked the management of both properties.

The suit of F. Augustus Heinze against A. D. F. Adams and other brokers for alleged conversion of Ohio Copper, Davis Daly, and other securities pledged by him with Adams, and repledged by Adams to eight or ten other persons in Boston, still drags along, and promises to rival the Thaw case in the raising of technical points and the protraction of litigation. Not long ago the court here handed down a decision that Heinze could not maintain his original charge of conspiracy against the brokers in whose hands his hypothecated securities were finally lodged, but intimated that he might hold some of the brokers separately for conversion, the suggestion being that Heinze's bill be amended from the allegation of conspiracy to that of conversion. The face value of the securities pledged by Heinze amounted to about \$350,000. Mr. Adams, the man with whom the securities were placed as collateral for loans, is now 'doing time' in the state prison at Charlestown. Some of the brokers have effected settlements and been released from litigation, and others have left the country. Henry Hovey Love, one of the indicted men, is understood to be living somewhere in the Northwest, having left Boston immediately after Heinze began his suit.

The recent strength of Greene Cananea is taken as an index of quieter conditions in Mexico. The Company has an immense property, but has never had the opportunity of operating in a stable manner and demonstrating what it could do in the way of costs.

It is reported lately that there has been some selling of Alaska Gold stock by one of the syndicate principals which

first brought the company to public attention. It is stated, however, that this selling is not from the estate of the late A. F. Holden, one of the engineers who examined and reported upon the property for the banking interests which have campaigned on the market. Mr. Holden, in his will, left specific instructions enjoining the executors of his estate from selling the securities of mining companies with which he had been identified professionally and financially. Under the terms of this injunction, it is understood that the Holden estate is not a seller of Alaska Gold.

When normal conditions are restored at the Lake district, we may expect some sensational news from Mayflower and Old Colony. As matters stand at present, there are reports of developments from both properties by drilling, but it looks like wasted ammunition to put it out with the continuance of the strike at the Lake. The latest news is that Old Colony's No. 27 drill has cut the Mayflower lode at a depth of 1796 ft., continuing to 1893 ft., a width of 93 ft. This compares with 77 ft. in the No. 26 drill. The latest showing is considered to be the best in the Old Colony territory. Besides, it has significance by way of extending the proved mineralization of Old Colony still farther to the south. It looks now as if the next market sensation at the Lake, *ex* the strike, will break out in the Mayflower-Old Colony quarter, and it may be that another swift campaign resembling that of a few years ago on Lake and Indiana may be pulled off.

TORONTO, CANADA

INDUSTRIAL DISPUTES LEGISLATION.—CANADIAN COAL & COKE Co.—NEW OIL REGULATIONS.—EIGHT-HOUR DAY EXEMPTIONS.—CANADIAN VENEZUELAN ORE COMPANY.

It is stated that, at the present session of the Dominion parliament, further legislation for the purpose of extending the scope of the Industrial Disputes Act will be introduced. This legislation for the prevention of industrial warfare will be more advanced than any similar legislation in any other country. At the present time the Industrial Disputes Act affects only those employees engaged in work on any public utility, and it is the intention to extend this act to take in all branches of labor, both public and private. The present act was designed to prevent strikes and lockouts until the matter under dispute had been considered and a finding arrived at by a board of conciliation and arbitration. Neither employers nor employees are bound to abide by the decision of the board, but the findings of the board in many cases have effected harmonious agreements and largely reduced the number of strikes and lockouts in the Dominion. The Minister of Labor states that much good can be accomplished by extending the scope of the act to include all labor. If this legislation comes into force, all public and private enterprises will be conducted under the jurisdiction of the department, and in case of a dispute arising, no strike or lockout will be permitted until a report has been made by the board of arbitration. Under the terms of the act, no employer will be allowed to dismiss or refuse to employ a man on the ground that he is a member of a labor union, nor will labor unions be allowed to call a strike on account of the employment of men who do not belong to unions. Severe penalties will be exacted in the case of employers or employees who do not live up to the provisions of the act.

The financing of the recently organized Canadian Coal & Coke Co. is making satisfactory progress, and it is expected that the Company will shortly be in a position to complete development work on the various properties and put them on a profitable operating basis. The temporary financing, which will provide sufficient funds for the payment of outstanding liabilities, and for putting three of the properties in full operation, is practically completed. For the permanent financing, an issue of \$3,000,000 14-year 6% serial bonds dated December 1, 1913, will be issued. To enable the Com-

pany to retire the bonds, a sinking fund will be started in 1915 which will be sufficient to redeem the entire issue by 1927. These bonds will constitute a first mortgage against all the properties of the Company. Reports of independent engineers acting for the bankers who are to undertake this financing, have placed a total value of \$17,900,000 on the plants and properties of the consolidated company. The proceeds of the bond issue will be utilized to retire the temporary financing and to provide working capital and funds for the extension of the plant. When all the necessary expenditures for plant and equipment have been made, it is estimated that the Company will have working capital amounting to \$250,000, in addition to an emergency fund of \$350,000. The different collieries are at present capable of producing 1200 tons per day, but when the new development has been finished and the new equipment installed, an output of 8000 tons per day can be attained.

The new Dominion oil regulations which have been prepared by the Hon. Dr. Roche, have been approved by the cabinet council. In these regulations there are several clauses of an imperial nature, which are intended to conserve the oil resources of Canada for the use of the British Government in time of war and emergency. One regulation requires that any company holding a lease on oil lands shall always remain a British company, registered either in Great Britain or Canada, and having its chief place of business in His Majesty's dominions. The chairman of the company and the majority of the directors shall always be British subjects, and the company shall not at any time become either directly or indirectly controlled by foreigners or a foreign corporation. The clause will enable the Crown to obtain in time of war, a reliable supply of oil fuel and also prevent speculators from taking advantage of an emergency to put a prohibitive price in force. Another section of the regulations gives the Crown power to assume control, in time of emergency, of any lease or works and to operate and maintain them, the compensation in such case to be fixed by the exchequer court. A further proposed clause prohibits all exports of oil from Canada in time of war. This clause, however, will necessitate a change in the export act by parliament, and the necessary legislation will probably be passed.

Following the report of the Minister of Mines, the Moose Mountain, Helen, and Magpie iron mines, in northern Ontario, have been exempted from the provisions of the eight-hour day which came into force on January 1, 1914. An investigation of these properties by the mine inspector showed that the conditions regarding safeguards for insuring the comfort, safety, and health of the miners were of a higher standard than in any other mines of the province. These three mines are the only ones which have been exempted from the provisions of the act.

At a meeting of the bondholders of the Canadian Venezuelan Ore Co., held in Montreal on January 20, a resolution was passed authorizing the recently appointed bondholders' committee to serve the trustee with notice of default on bond coupons due at the beginning of the month, the trustee for the bondholders being the New York Trust Co. This step is preliminary to winding up proceedings by the trust company. According to the provisions of the trust deed, the property will revert to the bondholders 60 days after the serving of the notice, unless in the meantime arrangements are made to pay the overdue interest. There was no discussion at the meeting of any plan for financing the Company, and as the bondholders and shareholders are practically identical, it is altogether probable that liquidation proceedings will be allowed to take their course. When the property has reverted to the bondholders, it is probable that some decision as to the future will be made. A drop in the market price of ore, and a serious decline in the grade below that estimated by the Company, is stated to be responsible for the Company's financial difficulties.

SALT LAKE CITY, UTAH

MILL CONSTRUCTION AND METALLURGICAL WORK AT PARK CITY. — PROBABLE SUCCESS OF A CHLORINATION PROCESS.—PLANTS IN OPERATION IN THE DISTRICT.

The current year will be a busy one in mill construction at Park City, Summit county. The erection of two new plants has been decided on, a third is probable, and an old plant, long idle, is to be restored to activity. The management of the American Flag has decided on chlorination as the process for treating its non-shipping ore. E. A. Wall is planning a mill for the Daly Mining Co. The old Glencoe property has been acquired by a new company which proposes to revamp the mill and operate it for the zinc and silver-lead content of the ore. A milling plant has come to be regarded as an indispensable adjunct of a successful mine at Park City. Even those which have large bodies of high-grade ore to draw on find that the production of a considerable tonnage of mill ore is inevitable in the course of development. The American Flag is the latest of the big mines to follow the fashion. The management estimates a reserve of more than 50,000 tons of \$10 gold-silver ore, and the daily production of 25 tons of mill ore removed in prospecting. G. H. Seibold, a metallurgical engineer, has been employed for the last six months in experimenting with the ore and investigating treatment methods. The first step taken in the investigation was to decide, once and for all, that no process would be considered which had not been carried to a successful and practical stage by others. Hence the work was confined to narrow limits. While it had been known for some time that the mill ore, constantly being added to by development, was peculiarly amenable, both physically and chemically, to the new chlorination process, yet this method of treatment was not looked upon with favor, because it was until recently in an experimental stage so far as successful appliances were concerned. While a description of this new process is not permissible at this time, it is a matter of common knowledge that it is a modernization of the old Augustin process, wherein the metals are converted to chlorides and subsequently leached with suitable solvents. The process as now perfected, notably by Theodore P. Holt, has overcome the previously existing difficulties in volatilization, low extractions, and high costs. While the management of the American Flag was watching the development of the chlorination process, it was carefully studying the results to be obtained by concentration, and concentration followed by cyanidation. Without going into detail in regard to the tests, it was found that concentration alone was unsatisfactory, and that a recovery of 36% of the silver, 49% of the gold, and practically all the lead was the best that could be expected. A combination of concentration and cyanidation gave a final extraction of 92% of the gold and 74% of the silver, consuming 3.4 lb. cyanide. Leaching with sulphuric acid before cyanidation also gave a fair recovery, with a reasonable cyanide consumption. Chlorination promises a recovery of 92% of all the metals at a lower cost than any of the other processes, and since this method of treatment is in practical operation, its adoption has been decided upon. As an original mill unit, to take care of the mill ore that is actually being broken each day in the process of developing the first-class ore, a plant of about 25 tons per day capacity is being considered. The mill will be regarded as experimental and to demonstrate the possibility of milling the ores, and will be so designed that its enlargement later may readily be accomplished. Its first cost is estimated at \$15,000 and the cost of treatment is placed at \$3.50 per ton. The choice of the Daly West in the matter of milling equipment has not been announced, and probably has not been made. The active mills of the camp at present are the Silver King Coalition, Daly-Judge, Mines Operating, and some small jigging plants along the stream running from the Daly-Judge mill.

JOHANNESBURG, TRANSVAAL

GOLD OUTPUT IN NOVEMBER.—LABOR SUPPLY.—THE PAST YEAR
A DISAPPOINTMENT.

November gold returns as published by the Transvaal Chamber of Mines were quite disappointing. The total working profits fell to £970,623, a lower figure, excluding the strike month, than has been reached for many years. The tonnage crushed was only 2,006,507, compared with 2,347,929 tons in January 1913. The most remarkable feature of the month was the reduction of working costs from \$4.36 to \$4.34 in November as compared with the first month of the year, in spite of the smaller tonnage milled. The fall in value of the output was from £3,353,116 in January to £2,860,788 in November, so that the decline in aggregate profits is easily explained.

Throughout the whole length of the reef there are complaints of the chronic scarcity of native labor, and several of the mines always hitherto popular with the natives are now considerably short of their full complement. It was anticipated that the new year would witness an improvement in the labor conditions in the Transvaal, but all these hopes have been clouded by the railway strike which commenced on January 8. The strike may not be altogether a general one, but some difficulty must result from only a partial service of trains, and the effect on the native labor supply will be anything but encouraging. The year 1913 has been a disappointing one for the gold mines all around, but 1914 promises to be even worse, the comparison with a year ago as shown above being distinctly disappointing.

KALGOORLIE, WESTERN AUSTRALIA

GREAT FINGALL DEVELOPMENTS.—THE LANCEFIELD TO HAVE ANOTHER CHANCE.—DIAMOND-DRILLING AT FRASER'S.—VICTORIOUS MINE.—DEVELOPMENTS IN THE HORSE-SHOE AND IVANHOE.

The Great Fingall mine, according to Hope Nicolson, the manager, is looking as well as it ever did. The peculiarity of the mine is that the ore is in lenses with intervening blanks. The first lens produced 30,000 tons yielding \$375,000, and cut out at an incline depth of 300 ft. The second lens extended from 460 to 1370 ft., and produced 1,822,500 tons, yielding \$23,165,000, out of which \$8,734,900 was distributed in dividends. The third lens was opened at 1900 ft., and is still going strong at 2500 ft. An internal shaft has been sunk from No. 13 level, 1500 ft. incline, and is now below No. 18 level, 2400 ft. incline. This shaft has been fitted with a 40-ft. head-frame, and hauling will be done by an air winch. At No. 15 level the ore-shoot is 144 ft. long and assays \$10.46 over a width of 6 ft. At No. 16 level the shoot has lengthened to 400 ft., and assays average \$10 for the width of the drift, 6 ft. At No. 17 level the shoot extends for 300 ft., averaging \$10, also for the full width of the drift. At No. 18 level, assays average \$11.20 for a length of 430 ft. Several winzes have been sunk below this level, and prove that good grade ore continues still deeper. The upper levels of the mine are practically depleted, but ore from the new lens will be available for treatment early in 1914, and it is anticipated that the mine will then resume regular dividends.

The Kalgoorlie & Boulder Firewood Co., which, with the West Australian Bank, was the largest creditor of the defunct Lancefield company, has taken over the mine, and put John Dustan, at one time metallurgist of the Associated mine, in charge. Mr. Dustan has since been inspector of state batteries, and recently mining superintendent and traveling inspector of the many mining interests of the Western Australian Mining Corporation, Ltd. The Lancefield mine is equipped with a practically new 40-stamp mill and plant consisting of Krupp ball-mills and Edwards roasting furnaces.

This has proved a failure owing to the presence of arsenic and graphite in the ore, the high cost of fuel, and the long distance it has to be carried by tram, as nothing but small mulga, a hard native tree with great heating capacity, is available. The mine has produced \$4,140,000 from 540,000 tons, or \$7.67 per ton, yet the whole of this sum, as well as \$500,000 working capital and \$200,000 of borrowed money, has been spent on the property. The ore reserves are estimated at 187,300 tons, assaying \$8.40 per ton, but this grade of ore has proved unprofitable under the old conditions. Firewood alone costs \$2.50 per ton of ore treated, owing to its scarcity and its quick-burning nature. Unless the treatment can be radically improved and cheapened, the new owners are unlikely to make the mine a commercial success. The lode on the property is 25 ft. wide, but, unfortunately, like the Gwalla Consols at Wiluna, and the Transvaal at Southern Cross, contains arsenic and graphite, and this makes its successful economic treatment difficult. The mine is opened by eight levels, the deepest being 1000 ft. on the incline, and when the whole ore-shoot is blocked out, it is estimated there will be 100,000 tons of ore at each level. The lode strikes northeast and southwest, and dips east at the flat angle of 40 degrees.

Diamond-drill boring at Fraser's mine at Southern Cross still continues under government supervision, and already four bores have been completed, the deepest to a depth of 1160 ft. Every bore has passed through lodes, but no details of the assay value of the ore has been published. No. 5 bore is now being drilled to cut the main lode at 400 ft. W. J. Loring, who took an option on the property before leaving for London, in May 1913, has given up the option owing to the unsatisfactory state of the London stock market. The Western Australian Government has already spent \$35,000 in boring, and is hardly likely to abandon the work unless it sees no hope of a successful issue.

Late developments at the Victorious mine, at Ora Banda, have not been satisfactory, and, so far as tested, the ore-shoot is short and far from fulfilling expectation. The lode was cut at 22 ft. from the shaft, instead of 50 ft. as anticipated, and the cross-cut is being continued to see whether it is the same lode or a new one. Winzes have also been started from No. 5 level to settle this point. Owing to the results, the price of shares is weak.

Early in December the east cross-cut at 2780 ft. in the

GOLDEN HORSE-SHOE MINE.

Horse-Shoe mine cut No. 4 lode, which proved to be 16 ft. wide, worth \$14 per ton. At the Ivanhoe a diamond-drill hole has been put in east from the 2870-ft. level station, at a depressed angle of 40°, to test the country surrounding the east lode. At a depth of 250 ft. in the hole the porphyry dike was cut and continued to 521 ft., when the quartz-dolerite was entered. The east lode was cut in the porphyry at a point equal to 263 ft. east of the shaft, and 3067 ft. in depth. It was 8¾ ft. wide, 2 ft. of which assayed \$2 per ton, and the balance traces.

General Mining News

ALASKA

FAIRBANKS

The annual meeting of the Newsboy Mining Co. was held at Fairbanks on January 18. Leslie M. Drury, the manager, stated that there was enough \$20 ore in sight to last three months. Some of it being mined was worth \$150 per ton. Work continues at the 100 and 300-ft. levels. Mining cost \$5 and milling about \$2.50 per ton. Wood at \$14.50 per cord makes the milling expensive, two cords per day being consumed. He proposed to install a 30-hp. gasoline engine for \$1500, and so reduce costs by 75%. Revenue from gold was \$36,979, and other receipts \$15,368. The surplus is \$18,864.

ARIZONA

COCHISE COUNTY

The annual report of the Employees' Benefit Association of the Copper Queen company shows the following data: Contributions from members, \$25,816; from Copper Queen company, \$8027; balance from 1912, \$21,334; total receipts, \$55,177; accidents on duty, 492; claims paid, \$5945; accidents off duty, 62; claims paid, \$1996; natural deaths, 9; claims paid, \$9675; sickness claims, Blsbee and Douglas, claims paid, \$15,557; and surplus at end of 1913, \$17,503.

GILA COUNTY

(Special Correspondence.)—The Inspiration flotation plant continues to work full time, and nine carloads of concentrate have already been shipped to the Cananea smelter. The Oliver filter is doing good work, and a Trent machine is to be tested. Retaining walls at the concentrator site are still unfinished. On the road to the property is another locomotive from the H. K. Porter Co., 32 gondola ore-cars from the Pullman company, and the large General Electric transformers.

During January an advance of 2057 ft. was made in the Miami mine, mostly in the Captain orebody. There was 102,522 tons of ore mined last month, and 102,497 tons milled, yielding 3,258,650 lb. of copper in concentrate. A pump has been installed to return water from the tailing area, to prevent the residue from flowing down the creek and interfering with irrigation.

Miami, February 14.

The Old Dominion Copper & Smelting Co., at Globe, will add to its electric mine equipment a 225-hp. induction motor from the General Electric Company.

The road between Globe and Copper Hill, a distance of three miles, is in a bad state, and taxpayers are asking for a new road to cost \$3000.

GRAHAM COUNTY

The Shannon Copper Co. reports as follows during the last quarter of 1913:

| | |
|--|-----------|
| Ore treated, tons | 72,617 |
| Copper output, pounds | 3,403,853 |
| Gold, ounces | 588 |
| Silver, ounces | 25,836 |
| Average price received for copper, cents per pound.. | 15.216 |
| Net profits | \$101,638 |
| Net assets, not including the railway | 396,255 |

The Shannon-Arizona railway made a net profit of \$6006 above bond interest requirements.

PINAL COUNTY

Gold-bearing ore has been discovered between Globe, in Gila county, and Ray, and the new camp has been named Gold Creek.

YAVAPAI COUNTY

(Special Correspondence.)—The Prescott Chamber of Commerce has prepared a complete list of properties in this county being worked, and prospects requiring capital, and will send this information free to anybody interested in mining. The list includes about 160 groups of claims, with information which might be of benefit in securing money for their development. Some properties are developed enough for the interests of capitalists, others are in the early stages of development, and the remainder are mere prospects which indicate good possibilities.

Prescott, February 11.

CALIFORNIA

AMADOR COUNTY

In a raise 200 ft. north of the west cross-cut on the 2600-ft. level of the Keystone mine, at Amador City, 6 to 8 ft. of good ore has been opened. The shoot is in slate, near the greenstone contact. A drift is being driven at 1200 ft. to cut a vein opened at 900 ft. About 20 in. of high-grade ore has been opened at 2100 ft. in the Bunker Hill. Prospecting at the Alpine, at Plymouth, is encouraging, and 3 ft. of ore has been opened. A new signaling device has been installed at the Argonaut, at Jackson, the invention of John Rule, superintendent.

ELDORADO COUNTY

(Special Correspondence.)—The Georgia Slide mines, at Georgetown, have been bonded to H. K. Montgomery. The property consists of five patented claims, the Brattie, Parsons, Pacific, Blue Rock, and Hanson, which have been worked continuously for 60 years. The dump of 3,000,000 tons will be drilled and sampled.

Georgetown, February 18.

INYO COUNTY

There is some activity in Death Valley at present, and the camp of Carbonite has sprung into existence. Developments to 300 ft. in the Carbonite mine, the principal property in the district, have proved ore containing gold, silver, lead, and copper. A wagon-road has been cleared across the south end of the valley, 41 miles to the Tonopah & Tidewater railway at Zabriskie. Sixty mules and a 25-ton traction engine are hauling ores for shipment to smelters.

NEVADA COUNTY

At the Premier mine, north of Grass Valley, an adit is in 800 ft. at a depth of 122 ft., and it is figured that another 150 ft. must be driven to cut the vein. Some rich quartz stringers have been cut in a cross-cut. Jesse R. Butler is superintendent.

PLACER COUNTY

The Placer County Land Co., of Auburn, has bonded 2½ miles of the Bear river bed to W. F. Englebright, of Nevada City, for \$50,000. The property will be drilled for gold for probable dredging operations.

Two and a half tons of black powder was exploded by electricity at the R. H. Genung gravel property, near Iowa Hill, on February 14. About 10,000 cu. yd. of gravel was loosened ready for sluicing. This district is showing increased activity.

SHASTA COUNTY

The Oro Water, Light & Power Co. is negotiating for the sale of several ranches below Redding for dredging purposes. Prospecting by drills has proved a large area of 10-cent gravel. The Field process plant at Redding is to be given a good trial. Rich gold ore has been opened at 200 ft. in the Silver King mine, in the Centerville district, four miles west of Redding.

SISKIYOU COUNTY

Forty-one tons of ore from the Osgood mine yielded \$2000 in January. Eleven men are employed. The Commore mine

has been reopened, and a 3-ft. shoot is being worked. It is hoped to start the old mill in April. The Siskiyou Mines Co. is to extend its ditches for water-supply. These are 16 miles long at present, and four giants are in operation.

TRINITY COUNTY

(Special Correspondence.)—At the Enterprise mine, under lease to R. A. Skinner and others, 10 stamps are crushing ore from the lower level. The vein is 30 in. wide, and yields \$20 per ton by amalgamation. Prospects at this mine are good. Ten men are employed. Recent floods carried away part of the lower dam, necessitating the mill being connected with the pipe-line from the upper flume, which has been used exclusively for electric light and air-compressor. There is plenty of snow in the mountains, and a long season is expected. The Hoodoo property, adjoining the Enterprise on the south, owned by Grant Day and James McLane, is under bond to Eastern people, who will commence further development soon. Some good ore has been produced from this mine, and the new work should open more orebodies.

Helena, February 15.

TUOLUMNE COUNTY

The Springfield Tunnel & Development Co.'s adit, 8 by 8 ft., is in 450 ft., and is being advanced 5 ft. per day. Twelve men and two Damas machine-drills are employed each 8-hr. shift. Rich ore has been opened in the Caverone mine, 4 miles East of Columbia, by Plummer brothers.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Dorrit mill, situated on Chicago creek, is to be provided with a cyanide plant. F. L. Patrick, the manager, states that the improvements will be made inside of 60 days. The new cyanide mill near the Saratoga mine dumps is nearing completion, and ore treatment will be started by March 1. S. S. Rowe is in charge. It is stated that a 50-ton electric smelter is to be constructed at the New Era mine at Freeland. H. A. Mills is in charge. Mrs. H. Ettie Minier, manager of the Little Giant G. M. & M. Co., states that work will be started during the next month in the construction of a large mill. The plant will be situated near the portal of the Commodore adit at Lawson. Ores will be treated from the White-Little Giant group of mines, situated on Red Elephant mountain. There was an increase of production in the Idaho Springs district for January of 35% over that of the same month of a year ago. The increase of tonnage was ten cars. A. H. Parker, of Denver, is now in charge at the Argo mill. The machinery is running two 12-hour shifts, and an average of 150 tons of ore is being treated per day. The Newton mine, on Chicago mountain, operated under lease by E. Smythe & Co., is the scene of a rich discovery. The orebody is 2 ft. wide, and was cut in the east drift driven from the bottom of the shaft. Assays show \$100 per ton in gold and silver.

Idaho Springs, February 3.

Construction work at the Edison mill, at Silver Plume, will probably be finished at the end of February. A new cable is to be fitted to the aerial tramway. Work has been resumed at the Centennial mine by the owner, David Kennedy, who intends to erect a 50-ton concentrating plant in the spring. The storage-battery locomotive installed at the Capital mine is working satisfactorily. Brandstetter and Moscript, Hummer and son, De Manters and Oldfield, and Oliver, lessees at the Capital, are busy prospecting and mining ore. A modern concentrating plant of 50-ton capacity is to be erected at the Centennial mine. The ore contains from \$3.60 to \$12 per ton in gold.

GILPIN COUNTY

The first shipment of pitchblende from the Central City district, a car of 12 tons, valued at \$144,000, arrived at Denver on February 17, consigned to the local representative

of Alfred I. Dupont of New Jersey. The ore is to be treated at a Denver testing plant before starting for New York, its final destination. The car was guarded by an armed escort on its journey to Denver. The mines from which the ore was taken were described by Forbes Rickard in this journal of June 7, 1913.

LAKE COUNTY (LEADVILLE)

The shipment of low-grade zinc ores from this district has always been unprofitable, and the want of a local plant to treat them has been often discussed here. Augustine and Jones, of Oklahoma, who are interested in zinc smelting in that state, have decided to erect a 50-ton smelter at Leadville as a first unit. They state that ores containing from 14% zinc upward will be received, but they must contain a certain percentage of iron. The Star claims, on Carbonate hill, are producing up to 1000 tons of ore averaging 7 to 10 oz. silver and 40% excess of iron per month. From the Waterloo, iron, lead, and carbonate of zinc ores are being shipped regularly.

OURAY COUNTY

Shipments of concentrate and crude ore from Ouray mines in January were as follows: Camp Bird, 540 tons; Wanakah (outside), 379; Wanakah (Brown mountain), 1325; Atlas, 176; Cumberland, 70; Barstow, 27; Bachelor lease, 42; San Juan Metals Co., 11; and Arps Krisher, Wedge lease, 47 tons. The smelter shipped 178 tons of matte and 12 cars of limestone was sent to the smelter from the Ouray quarry.

SAN JUAN COUNTY

Shipments of ore from the Dives, Arastra Leasing Co., E. Plant, Gold Tunnel, Mayflower Leasing Co., Aspen, and Primrose Leasing Co. properties, at Silverton, during the first 25 days of January, amounted to 575 tons; while concentrates from the Gold King, Iowa Tiger, Sunnyside, and Intersection totaled 775 tons. Sampling the Green Mountain mine by H. B. Barling and G. A. Jahn, Jr., of New York, is finished. A large tonnage of low-grade ore has been opened.

TELLER COUNTY (CRIPPLE CREEK)

Good progress is being made in sinking No. 1 and 2 shafts of the Portland mine. They are down 1625 and 1730 ft., respectively, the latter being deepened about 130 ft. in three weeks. A company, to be called the Mineral Hill Ore Reduction & Leasing Co., is to be formed by A. H. Heller, for the purpose of securing leases and erecting a cyanide plant in the district. Options have already been acquired, and a site for a mill chosen. New rolls are being installed in the Gaylord mill. The Isabella Mines Co. held its annual meeting at Colorado Springs on February 4. The superintendent, John T. Hawkins, who recently resigned, reported that the Comet vein has been opened 125 ft., where it is 4 ft. wide of oxidized ore. On No. 9 level an ore-shoot has been opened, and the drift and raise are in granite breccia worth \$8 to \$12 per ton. Revenue during 1913 was \$254,165, and net profit \$7129. There are 31 sets of lessees working, who shipped 18,288 tons of ore worth \$243,252. It is reported in Colorado Springs that the Portland company may erect an electric power-plant on its property on Battle mountain. The Elkton company is to lease certain blocks of ground from No. 11 level to the surface. According to the superintendent, R. P. Windsor, royalties will be as follows:

| Value of ore per ton. | Per cent. |
|-----------------------|-----------|
| \$10 and under | 10 |
| \$10 to \$20 | 15 |
| \$20 to \$30 | 20 |
| \$30 to \$50 | 25 |
| \$50 to \$80 | 35 |
| \$80 to \$100 | 40 |
| \$100 and over | 50 |

This property has produced nearly \$11,000,000 and paid \$3,279,460 to date. At the annual meeting of the Company, held on February 10, the question of extending the Roosevelt

drainage tunnel was discussed. It was proposed to drive it a farther 2200 ft., but only 5 by 6 ft. in area. At this point a hard basalt dike would be opened, allowing of rapid drainage of the mines west of the dike.

IDAHO

SHOSHONE COUNTY

A new shoot of copper sulphide ore has been opened by a raise from the 200-ft. level of the National mine, near Mullan. The ore contains 6 to 8% copper, and good silver content. The annual meeting of the Tamarack & Custer Consolidated Mining Co. was held last week at Wallace. The ore goes to the Tacoma smelter, and shipments in 1913 were worth \$366,072. Operating and construction expenses totaled \$303,308. Cash in banks amounts to \$64,601. Retimbering the Frisco mine, after its being unwatered, is finished, and overhauling the mill is nearly complete.

ILLINOIS

The petroleum production of this state in 1913 was estimated to be 21,600,000 bbl., against 28,601,308 in 1912, according to Raymond S. Blatchley, of the State Geological Survey. The total since 1904 is 208,112,868 bbl., valued at \$153,431,078. The decline in output, which began in 1913, seems to correspond with the decrease in new development in the deep Lawrence county pools. The sands of this district have a good staying quality, and are expected to yield abundantly for many years. The present rapid drop in their yield is normal, and later the decline should continue at a much lower rate. About September 1, 1910, stocks of oil in the state amounted to 29,289,164 bbl. The decrease in this surplus has been about 16,000 bbl. per day since February 1913, against 19,500 bbl. until August 1912 and 23,400 bbl. to February 1913. A general advance in prices of Illinois oil has accompanied the decreased output and surplus, due chiefly to the demand for motor fuels and other economic conditions. The present price is \$1.45 per barrel against 67c. in January 1912. There were 1439 producing wells in 1913.

MICHIGAN

Houghton County

At the Calumet & Hecla, 27 stamps are working, crushing 9000 tons per day; five at the Osceola, crushing 3000 tons; two at the Ahmeek, handling 1300 tons, and five at the Quincy, treating 3200 tons.

MONTANA

Silverbow County

During January, the Butte & Superior mill treated 33,520 tons of ore, yielding 11,117 tons of concentrate, containing 51% zinc, with a recovery of 90.67%. The results in this month of 1912 were 18,100 tons, 5694 tons, 46.36%, and 66.77%, respectively. The cost of mining and treatment during the past six months of 1913 was under \$5.50 per ton, and the net operating profit over \$5 per share per year.

The Anaconda Copper Mining Co. has ordered one 35 and three 75-hp. motors. The East Butte Copper Co. has ordered a 150-hp. induction motor. The Butte Duluth Mining Co. will place in operation next power plant a 1250-kva., two-unit, three-bearing, synchronous motor-generator set, three 150-kva. transformers, and a switchboard, also seven motors ranging from 5 to 150 hp., all the apparatus having been ordered from the General Electric Company.

NEVADA

Clark County

(Special Correspondence.) The St. Anthony Mining Co. is operating a mine in the Yellow Pine district, 2½ miles west of Good Springs. The property consists of about 140 acres, and ore shipments from December 26, 1912, to January 7, 1914, were 897 tons yielding net returns, after paying freight and treatment charges, of \$27.75 per ton. The principal work of

late has been at the east end of the Columbia claim. The incline shaft is down 175 ft., and a cross-cut at 150 ft. has produced most of the ore. Development at present shows 6 to 15% copper ore, there being 8 ft. of 12% ore at 150 ft. depth. The shaft will be sunk to 200 ft., and cross-cutting done. Several years ago the old workings yielded ore worth \$30,000, and this part of the mine has been equipped for production. A compressor, machine-drills, auto-truck and 5-ton trailer, and other equipment are necessary for a further reduction of costs. The 900-ft. aerial tramway reduced ore transport by 75c. per ton. Joseph Dederichs is general manager.

Other regular shippers at Yellow Pine are the Yellow Pine, Monte Cristo, Potosi, Anchor, Bullion, Singer, Hoosier, Keystone, Porter-Palace, and Frederickson.

Good Springs, February 5.

Humboldt County

According to Joseph Nenzel, the Mexican company, operating at Virginia City, will not erect the proposed mill at Rochester. Reasons for this are stated to be doubt as to ability to secure 90% of the silver in the ore, and the company will not make any contract which might be hampered by litigation.

Lincoln County

A bonus system to aid shaft-sinking at the Amalgamated Pioche has given good results. For each foot over 21 ft. sunk each week the men get \$1, and if over 100 ft. in a month an additional similar amount per foot. The shaft is down about 1350 ft. Lessees in the Pioche district are busy shipping ore.

Lyon County

The Mason Valley smelter received only 2671 tons of ore during the week ended February 14, and shipped four cars of blister copper. Two men were injured in furnace explosion Feb. 15. The tonnage shows a considerable falling off of late. Most of the ore being shipped from the Nevada-Douglas property comes from the Casting Copper claim, which averages 7 to 8% copper. Diamond-drills have proved three new orebodies in this part of the mine. The Ludwig produces a carload of 10% ore per day. Experiments being made on the ore at Denver, Colorado, will be finished by March.

Nye County

Ten mines at Tonopah produced 10,995 tons of ore worth \$264,440 during the week ended February 14. In January, the Belmont mill treated 15,009 tons, yielding 333,083 oz. bullion, with a net profit of \$150,288. Work on the new vein on No. 12 level opens about 3 ft. of rich ore. The Tonopah company's mill at Millers treated 12,255 tons, yielding 221,146 oz., and concentrate worth \$42,460. The net profit was \$119,423. The Jim Butler company's January profits were \$14,375. Six feet of ore is being opened in a winze below the West End 600-ft. level. In the Extension a raise above the 950-ft. level and a winze below it are opening good ore in the Murray vein. One stope on the MacDonald vein, in the Montana-Tonopah, is 60 ft. long and 8 ft. wide. This ore has a high gold content, the concentrate averaging 20 oz. per ton, and the mill bullion being much higher in this metal than the usual ratio of 950 to 10 or 15 per 1000 parts in this district. No. 1 shaft of the Buckeye-Belmont is making 17,000 gal. of water per 24 hours. A triplex electric pump is to be installed.

Ten stamps at the War Eagle mill, at Manhattan, are working, and the new equipment of ore-bins, 10 stamps, tubemill, and copper plates is to be started in a few days. A large tonnage of ore has been proved in the Mustang, which is sending it regularly to the War Eagle mill. There is an increasing quantity of the Maris chalcodony being quarried and used in tubemills in Nevada mining districts. A machine has been installed at the quarry to wear off the sharp corners of the rock before shipment. Better weather has resulted in a resumption of work at the placer areas.

A herd of 1800 sheep was grazing at Millers, 12 miles from Tonopah, last week, when they drank some water flowing from one of the treatment plants or tailing areas situated there, resulting in the death of 1200, worth about \$4800.

STOREY COUNTY

In a raise above the 2400-ft. level in the Ophir mine, 6 ft. of \$56 ore has been opened. Shares rose in price considerably as a result. T. F. McCormick is superintendent. The water in the joint Crown Point and Belcher incline winze was 135 ft. below the 1500-ft. level last week. Byron Jackson pumps are employed in unwatering.

WHITE PINE COUNTY

It is said that the Ruth mines may be reopened, and ore extracted by steam-shovels, although up to the present the property has been mined by underground methods.

NEW MEXICO

GRANT COUNTY

The Chino Copper Co. reports as follows for the last quarter of 1913:

| | |
|--|------------|
| Overburden removed, cubic yards | 934,088 |
| Ore milled, tons | 512,450 |
| Average copper content, per cent..... | 2.08 |
| Recovery, per cent | 65.54 |
| Copper output, pounds | 13,970,438 |
| Copper on hand and in transit, pounds..... | 20,844,497 |
| Profit | \$812,087 |
| Dividends paid | 645,405 |

Of the ore treated, 76.6% came from the southeast, 16.7% from the northeast, and 6.7% from the northwest orebody. A more uniform character of ore can now be mined. The concentrate cleaning plants were completed, producing a bet-

CHINO MILL WHEN BUILDING.

ter smelting quality. The water-supply is now satisfactory. Bonds were retired during the quarter, and those outstanding will be called in by July 1, 1914.

VALENCIA COUNTY

(Special Correspondence.)—A leaching plant of 100 tons capacity is to be built in the Zuni mountains near Sawyer, New Mexico, to treat copper carbonate ore. The process has been demonstrated in a small plant, and, if it is satisfactory in the unit now planned, a larger mill will be built.

Las Vegas, February 10.

OREGON

BAKER COUNTY

The Cornucopia Mines Co., at Cornucopia, will install two 75-hp. motors and controller recently ordered from the General Electric Company.

JACKSON COUNTY

(Special Correspondence.)—The Beaver Portland Cement Co.'s new plant to manufacture cement from the limestone

deposits near Gold Hill, is making good progress. Machinery is arriving, and is being installed. The rotary kiln is 20 ft. long and 10 ft. diameter. Five large 'slurry' tanks, 20 ft. high, being built from native fir, will hold the pulverized kiln feed from the crushers. Work at the quarry continues. The Company has several contracts for cement highways in the state.

Philomath, February 13.

SOUTH DAKOTA

LAWRENCE COUNTY

The State Tax Commission has issued a statement showing the taxes paid by the Homestake Mining Co. during the years 1905 to 1913, inclusive, which are as follows: \$76,987, \$76,512, \$72,837, \$80,430, \$92,617, \$96,261, \$103,939, \$108,482, and \$200,072.

TEXAS

EL PASO COUNTY

The El Paso smelter is being enlarged at a cost of about \$250,000. The present plant consists of six furnaces for lead ores, with a capacity of 200 tons each, and three furnaces for copper ores with a capacity of 300 tons each per 24 hours. The matte and slag from the copper furnaces flows into 14-ft. settlers, the slag being taken by a tram to dumps. Improvements are being made in the slag department. There are five 22-ft. diameter Wedge roasting furnaces in the copper department, each with a daily capacity of 200 tons. Three more Wedge furnaces, with two more hearths, making five each, are being installed. In the reverberatory plant are two oil-fired furnaces, each 19 by 95 ft., with a capacity of 350 tons each per day. Oil consumption is 300 bbl. each daily. Seven steam locomotives and about 50 cars are used about the plant. The power house contains all the necessary steam, electrical, and blowing machinery, while a machine shop is fully equipped. Over 10,000 determinations are made in the laboratory each month. At present about 1100 men are employed, including 200 to 300 on new work. The monthly payroll is over \$75,000, about \$60,000 is paid to El Paso houses for supplies, and the railroad companies receive from \$80,000 to \$100,000 for freight according to the *El Paso Herald*. A complete hospital is maintained at the smelter. The plant is operated by the American Smelting & Refining Co., and ores are received from all parts of Arizona and Mexico.

UTAH

JUAB COUNTY

Ore shipments from Tintic during the week ended February 13 were as follows: Mammoth, 33 carloads; Centennial-Eureka, 24; Chief Consolidated, 21; Eagle & Blue Bell, 17; Iron Blossom, 15; Grand Central, 12; Gemini (Keystone), 7; May Day, 5; Beck Tunnel, 5; Gold Chain, 2; Colorado, 2; Minnie Moore lease, 1; Uncle Sam, 1; Victoria, 1; Showers lease, 1; and Bullion Beck, 1; a total of 148 carloads.

SUMMIT COUNTY

Concreteing the Silver Hill underground station, in the Alliance adit of the Silver King Coalition, is well under way. A motor weighing 11 tons, to be used in this station, is at the mine. By April sinking the shaft should be started. Ore shipments from Park City during the past week were as follows: Silver King Coalition, 1050 tons; Daly-Judge, 435; Silver King Consolidated, 198; American Flag, 57; and Daly West, 50; a total of 1790 tons.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Republic Mines Corporation, which owns the Surprise, Lone Pine, and Pearl mines, at Republic, has been declared a bankrupt in the federal court at Spokane. The Knob Hill company produced ore netting

\$140,000 in 1913. The Belcher Mining Co., of Belcher camp, has been shipping 24 cars of ore per week from above the 300-ft. level. Thirty men were employed, but some have been laid off, as the smelters are not able to take all the ore. The British Columbia Copper Co. is sending a car of ore per day from the Lone Star and Washington mines, in the north end of the county, to its smelter at Greenwood. The Laurier Mining Co., in the Orient district, has completed its adit to the vein, 150 ft. farther than the pitch of the vein in the shaft indicated. A good body of ore has been developed in the Iron Creek mine, 40 miles south of Republic, and a shipment is being made to the Trail smelter.

Republic, February 10.

OKANOGAN COUNTY

(Special Correspondence.)—J. L. Harper, former general manager in Republic, of the Republic Mines Corporation, the Emperor-Quilp, and North Washington Power & Reduction companies, has secured control of the Golden Chariot mine, on Kruger mountain, and is negotiating for two other groups adjoining it. He is employing eight or ten men and getting out ore for shipment.

Oroville, February 12.

STEVENS COUNTY

(Special Correspondence.)—The Silver Queen mine, at Turk, is to be reopened. The ore is worth \$30 per ton, but it costs \$21 to send it to the Tacoma smelter. Good copper ore has been opened at 18 ft. in the Lena mine, near Rock Cut. At Chewelah, the Security Copper Co. has resumed work and will sink its shaft to 400 ft. A smelting plant to cost between \$35,000 and \$50,000 will probably be erected by the Copper King company.

Chewelah, February 11.

WYOMING

Reports are to hand of the discovery of very rich gold-bearing ore in the Snowy Range district. Assays, up to \$19,833 per ton, are so high as to warn miners from rushing to the place.

LINCOLN COUNTY

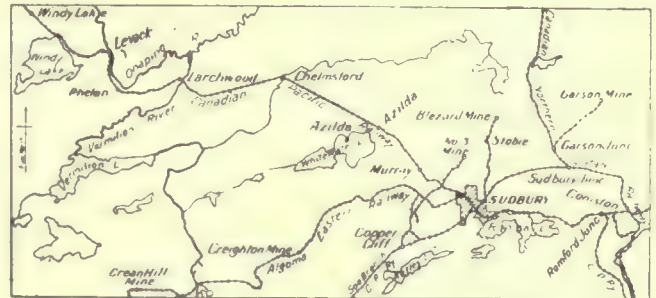

The new 50-ton mill of the United States Phosphate Co., at Border, in the Bear River valley, and one mile from the

valley in Utah, Idaho, and Wyoming. The largest and most easily worked deposits are said to be in Rich county, Utah, but as the distance to the railroad is greater than in Wyoming and Idaho more development is being done in the other two states.

CANADA

ONTARIO

Rich ore has been opened on the 200-ft. level of the Peterson Lake company's Kerry claim. Sixty men are erecting the transmission line from the power-station at Charlton to the Tough-Oakes mine at Kirkland Lake. The contract calls for the delivery of 800 hp. on May 1, and the work is being financed by the mining company, to be paid back by a rebate on power consumed. The annual report of the Dome Lake Min-

SUDBURY DISTRICT, ONTARIO.

ing & Milling Co. shows that 4645 ft. of development was done, of which 926 ft. was in ore. There are two ore-shoots on the 180-ft. level, 60 and 50 ft. long, 23 and 20 in. wide, worth \$17.96 and \$18.80 per ton, respectively. The 150-ft. level shoot has been opened 100 ft., assaying \$22.80 per ton. Ore treated during 1913 was 3717 tons, yielding \$18,762 by amalgamation, and \$5607 by concentration. The 10-stamp mill worked three months. A sorting table is to be installed, and so increase the value of the ore.

Monthly returns from the Dome mine have had the following averages since April last: \$13.11, \$13.68, \$8.69, \$6.81, \$6.31, \$6.50, \$9.56, \$8.76, and \$7.93 per ton.

A scheme to provide the towns of Copper Cliff and Frood with water at a cost of \$200,000, and provide for a population of 17,000 people, has been completed by the Canadian Copper Co. Three lakes, known as Meat Bird, Peggy, and Leach, near the Creighton mine, contain good water, and a watershed of 2660 acres surrounding the lakes has been secured. Pipes of 10 and 11-in. diameter will carry the water, by gravity, to Copper Cliff, where there will be a 100,000-gal. storage tank. Lady MacDonald and Clara Belle lakes have hitherto supplied Copper Cliff, but will supply the Company's smelting and refining plants in future, although both systems may be connected at any time. Whitson lake, 4½ miles northeast, will supply Frood. A watershed of 12 square miles has been secured around it. A 10-in. pipe, 22,000 ft. long, will carry the water to a 100,000-gal. tank. This supply must be pumped the whole distance.

CHILE

The Braden mills treated 98,000 tons of 2.15% copper ore in January, with 72.7% recovery, yielding 2,430,000 lb. of copper.

COSTA RICA

The Abangarez Gold Fields company reports as follows for December 1913: Ore treated, 7541 tons, gold recovered by amalgamation and cyanidation, \$53,828; profit, \$2343; expenditure on plant, etc., \$3987. The past year resulted in the treatment of 69,346 tons of ore, yielding \$579,236, and a loss of \$22,040. Betterment expenses were \$72,733. In 1912 the loss was \$128,682, and betterment expenses \$222,781.

MAP SHOWING PHOSPHATE AREAS OF IDAHO, UTAH, AND WYOMING.

Idaho boundary line, is ready for work. So far, crude ore has been shipped to Los Angeles, California; but it was found necessary to produce proper shipping material, so the mill was built. The Company is working a large phosphate deposit. There are other known deposits, mostly in the Bear Lake

DUTCH GUIANA

(Special Correspondence.)—The government of this colony has recently published the gold output for 1913, which amounted to 856,768 gm. (27,640 oz.), against 716,487 gm. (23,110 oz.) in 1912. About 90% of this gold was produced by hand methods. At present there is one small Chilean mill and one small dredge working in the colony. There will be another boat operating early in March. All gold produced in this country must pass through the government, which collects 5% of it. The figures given are quite reliable.

Paramaribo, January 30.

MEXICO

Of over 30 mines belonging to the American Smelting & Refining Co. in this country, only about five are being worked at present. Conditions in northern Mexico are improving.

AGUASCALIENTES

The American Smelting & Refining Co. has two blast-furnaces, or 50% of the total capacity, in operation at the Aguascalientes plant.

CHIHUAHUA

The Chihuahua smelter is working at 50% capacity again. Railroad communication is improving, but there is difficulty in procuring cars. Most of the ore being smelted is from the American Smelting & Refining Co.'s mine at Santa Eulalia.

SAN LUIS POTOSI

The American Smelting & Refining Co. has been trying to start its Matahuela smelter, but has not succeeded so far.

SONORA

Exports of ore and concentrate from this state in January, through the 'port' of Agua Prieta, were as follows: From Nacozari, 12,690 tons; El Tigre, 164; San Ygnacio, 55; Santa Rosa, 62; El Temblor, 17; Mina Cobre, 11; La Union, 16; San Jose, 32; La Caridad, 29; La Sonora, 51; Alemanita, 26; San Cristobal, 2; El Carmen, 22; San Francisco, 21; and Cobre Verde, 18; a total of 327 cars equal to 13,216 tons. The estimated value of the exports in Mexican currency was: copper \$1,984,800; silver, \$617,500; and gold, \$208,900; a total of \$2,811,200.

Several hundred armed Yaqui Indians are said to be wandering around the Arizpe and Sahuaripa districts, and molesting people in many ways. One treatment is to strip their victims naked and force them to enter the nearest pueblo.

NICARAGUA

The Tonopah Mining Co., of Nevada, has taken an option for a year on a property in this country. It has been favorably reported on by J. E. Spurr, the Company's consulting engineer. The Eden Mining Co. will be formed to develop the area.

PERU

Trials made of the new hydro-electric power-plant of the Cerro de Pasco Mining Co. are reported to have been satisfactory. Water is obtained from the Montaro river, and is conducted through a ditch and pipe about 12 miles to the station at Oroya, which is 70 miles from the smelter and Cerro de Pasco. Six Pelton wheels are connected in pairs to three generators of 3000 kw. each. The effective head of the water is 750 ft. The transmission line has been extended to Morococha, 15 miles from Oroya, to supply the Morococha Mining Co. The power-plant cost about £200,000 and was installed by A. L. Wilcox.

SIBERIA

Sakhalin has long been known to contain oil, and determined efforts are now being made to develop the territory by the Sakhalin Oil Fields, Ltd., a British company. The fields were examined for Prince Radziwill in 1909 by Paul Dvorkovitz, who gave a favorable opinion, and they were later studied by members of the staff of Sir Beverton Redwood.

Personal

A. E. DRUCKER is in Paris.

E. H. LESLIE is at St. Louis.

L. H. WEBB has returned from a European trip.

ROBERT ANDERSON is in Peru for S. Pearson & Son.

P. D. BURTT is at Grass Valley on examination work.

PERCY L. FEARN has arrived in New York from Costa Rica.

N. B. KNOX is at Kingston, Jamaica, returning from Colombia.

C. S. HALEY has returned from Colombia and is in New York.

CHARLES JANIN has gone to Russia to make a mine examination.

J. M. LILLIGREN passed through San Francisco returning to Nevada.

R. B. BRINSMADE is studying the economic geology of Jalisco near Guadalajara.

E. S. McCURDY has returned from New York and was in San Francisco last week.

WALTER A. SCHMIDT has returned from Europe and was in San Francisco Wednesday.

E. C. KLINKER was in San Francisco, returning from Los Angeles to the Eagle Bird mine.

THOMAS A. VARDEN, general superintendent for the Corbin Copper Co., at Butte, is at Salt Lake City.

G. M. COLVOCORESSES, general manager for the Consolidated Arizona Smelting Co., is at Humboldt, Arizona.

W. B. OREM, who has for many years been inspector of mines for the state of Montana, is at Bisbee, Arizona.

CARL J. TRACERMAN, of Butte, Montana, will take charge of the milling operations of the Bully Boy company, of Marysville, Utah, after March 1.

J. P. MONTAGUE has resigned his position as mill superintendent for the Tonopah Extension Mining Co. and will be succeeded by E. M. KIRCHEN, brother of J. G. KIRCHEN, the manager.

E. M. DE LA VERGNE, former vice-president and general manager of the Elkton Consolidated Mining & Milling Co., has been appointed superintendent of the United Gold Mines Co. to succeed EBEN BEERE.

Schools and Societies

The Columbia branch of the AMERICAN INSTITUTE OF MINING ENGINEERS held its quarterly meeting at Spokane on February 13. This consisted of reading and discussing papers and a smoker given by the Spokane Mining Men's Club.

The UNIVERSITY OF ILLINOIS COLLEGE OF ENGINEERING was recently lectured by Francis S. Peabody on 'The Mining and Utilization of Illinois Coal.' Illustrations included motion pictures of actual underground work, these being the first motion pictures taken in a mine.

The San Francisco branch of the MINING AND METALLURGICAL SOCIETY held a meeting, following a dinner at the Engineers Club, Hotel Sutter, on February 12. W. E. Colby addressed the members on 'The Beginnings of Modern Mining Law in Relation to the Revision of American Mining Law.'

Forty members of the AMERICAN INSTITUTE OF MINING ENGINEERS met at Wilkes-Barre, Pennsylvania, on January 31, to discuss the formation of a local section in the anthracite region. Those present were C. F. Rand, Joseph W. Richards, H. M. Chance, Bradley Stoughton, R. V. Norris, F. W. Chase, C. F. Huber, R. J. Foster, F. A. Hill, and others.

The Metal Markets

| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, February 19.—The market for all metals is dull. Copper has a downward tendency, while lead and spelter show no change for the past two weeks. Dealings in copper shares were brisk on the Stock Exchange. The total stocks of all kinds sold today was 429,621. Metal prices in London were: copper closed steady at £65 for spot, off 2s.6d., and £65 10s. for futures, off 2s.6d.; spelter, £21 7s.6d., unchanged; and lead, £19 10s., up 2s.6d. The bull movement in stocks generally has been checked. The issues in January were about £215,000,000.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | | Date. | |

| May | 60.21 | | Nov. | 58.76 | |
| June | 59.03 | | Dec. | 57.73 | |

In the earlier part of the week ended January 29, according to Pixley & Abell, the market showed steadiness and the rates were easily maintained. On the 27th, prices advanced to 53.5c. for cash and 53.8c. for forward, but they have since fallen away to today's quotations of 53.8 and 53.2c. respectively. The steadiness was almost entirely due to the liquidation of Indian bear accounts, a large amount being covered on the 27th, but there has since been a little Eastern selling, and, with the Indian support withdrawn, prices have sagged to the above quotations, at which the market closes quiet. The United States Mint bought 300,000 oz. on the 24th, and a small amount has been taken for the Continent. Supplies generally continue small, and, unless China opens weak after the holidays, rates should hold at about the present level, until some new factor presents itself.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| | 1913. | 1914. | | 1913. | 1914. |
|------|-------|-------|-------|-------|-------|
| Jan. | 50.45 | 37.85 | July | 40.70 | |

| May | 49.10 | | Nov. | 39.77 | |
| June | 45.10 | | Dec. | 37.57 | |

Tin witnessed one of the sensational movements which have characterized this metal from time to time, during the week ended January 24, when it advanced £9 per ton in London, according to Henry R. Merton & Co. The price jumped to £179, but on a good deal of realizing, it fell to £174 5s. for cash and

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

DOMINION STEEL CORPORATION

THE past year's output of the Dominion Steel Corporation, Canada, was as follows:

| | Tons. |
|--------------------------------|-----------|
| Coal mines..... | 5,100,000 |
| Iron ore mines..... | 780,000 |
| Limestone quarried..... | 582,000 |
| Pig iron produced..... | 357,000 |
| Steel ingots produced..... | 347,000 |
| Rails..... | 175,000 |
| Blooms sold..... | 32,000 |
| Wire rods made..... | 32,000 |
| Wire and wire products..... | 24,000 |
| Steel bars, etc..... | 16,000 |
| Sulphate of ammonia..... | 5,000 |
| Basic and granulated slag..... | 25,000 |
| Tar, gallons..... | 5,650,000 |

The steel plant has received several big orders, and is running full time.

QUICKSILVER production in the United States in 1913 showed a decrease of 5383 flasks compared with 1912, when the output was 25,064 flasks, according to the U. S. Geological Survey. California produced 15,396 flasks, and Arizona, Nevada, and Texas a total of 4285 flasks. The average price at San Francisco in 1913 was \$39.33 per flask, against \$42.05 in 1912. Exports were 1099 and imports 2032 flasks.

PIG IRON PRODUCTION in the United States during January was 1,878,786 tons, which is 97,352 tons less than in December.

Monthly Copper Production

AHMEEK COPPER MINING CO., Kearsarge, Michigan. \$1,250,000 in \$25 shares; 24,796 shares owned by Calumet & Hecla; 1800-ton mill at Hubbell; concentrate smelted by Calumet & Hecla smelter. Total in 1913, 9,100,000 pounds.

ALLOUEZ MINING CO., Allouez, Michigan. \$2,500,000 in \$25 shares; controlled by the Calumet & Hecla, which owns 43,000 shares and \$250,000 in notes of the Company; ore is milled by the Lake Milling, Smelting & Refining Co., in which the Allouez owns half. Total in 1913, 4,200,000 pounds.

ANACONDA COPPER MINING CO., Butte, Montana. \$108,312,500 in \$25 shares; controlled through Amalgamated Copper Co. by Thos. F. Cole, J. D. Ryan, and Standard Oil interests; 10,000-ton concentrator and smelter at Anaconda; 5000-ton concentrator and smelter at Great Falls, Mont.; also 70-ton electrolytic refining plant at Great Falls. Production figures include copper from all companies which ship custom ore to Anaconda smelters.

WOLVERINE COPPER MINING CO., Kearsarge, Mich. \$1,500,000 in \$25 shares; owns \$80,000 interest in Michigan Smelting Co.; controlled by J. R. Stanton; mill on Traverse bay treated 388,500 tons during last fiscal year. Total in 1913, 4,488,000 pounds.

Company Reports

SAN TOY MINING COMPANY

This Company operates in Chihuahua, Mexico, and the balance sheet for the year ended December 31, 1913, shows the following:

| | 1913. | Changes. |
|---------------------|-----------|-----------|
| Gross income | \$317,332 | +\$15,814 |
| Net earnings | 132,428 | + 25,971 |
| Surplus | 17,428 | - 29,029 |
| Total surplus | 513,229 | + 34,928 |

UTAH COPPER COMPANY

The fourth quarter of 1913 shows that the two mills treated 2,113,080 tons of ore, assaying 1.2165% copper, and yielding 31,982,442 lb. of copper. The total output for the year was 119,939,809 lb. The metal sold realized 14.857c. per pound. Copper on hand and in transit at the end of the period amounted to 39,854,993 lb. Financial results were as follows:

| | |
|---|-------------|
| Profit from milling | \$1,479,787 |
| Other income | 27,365 |
| Dividends from Bingham & Garfield railway..... | 175,000 |
| Dividends from Nevada Consolidated company..... | 875,437 |
| Total profit | \$2,557,590 |
| Dividends paid | 1,187,760 |
| Net surplus for quarter | 1,369,830 |

SIMMER & JACK PROPRIETARY MINES, LIMITED

This Company owns a considerable property in the Transvaal. The capital is £3,000,000, in 3,000,000 shares of £1 each. The report covers the year ended June 30, 1913. There was a total of 938,103 tons of ore mined. The fully developed profitable ore reserve was estimated at 2,524,000 tons, of an average mine grade of \$5.40, and 406,000 mine tons of partly developed ore worth \$4.70 per ton. Besides this reserve, there is still a considerable tonnage available for stoping from the upper levels and from foot and hanging walls of old stopes, which will be credited to the reserve as the ore is mined. As compared with last year, there was an increase of 48,700 tons milled, the recovery value and working costs being lower by 66c. and 18c. per ton milled, respectively, the net result being a working profit of £466,040, or £60,966 less than for the previous year. The profit from operations for the year was £471,954. Two dividends of 7½% each were declared, amounting to £450,000.

CHIEF CONSOLIDATED MINING COMPANY

This Company operates at Eureka, Juab county, Utah, and the report covers the year 1913. This may be tabulated as follows:

| | |
|--|-----------|
| Development, feet .. | 6,383 |
| Ore shipments, tons .. | 51,173 |
| Metal contents: | |
| Gold, ounces | 4,751 |
| Silver, ounces | 1,017,107 |
| Lead, pounds | 2,584,857 |
| Copper, pounds | 114,305 |
| Revenue, after paying transport and smelting costs.. | \$376,827 |
| Balance from previous year | 303,023 |
| Sundry receipts | 18,870 |
| Total | \$698,720 |
| Mining costs | \$264,239 |
| Dividends | 175,307 |
| Other expenses | 44,112 |
| Balance at end of year | 215,062 |

TONOPAH MIDWAY MINING COMPANY

During the year ended December 31, 1913, the Tonopah Midway Mining Co.'s work showed the following results:

| | |
|---|----------|
| Development, feet | 3,790 |
| Total to date, feet | 41,853 |
| Ore produced in 1913, tons | 2,141 |
| Value per ton | \$20.418 |
| Costs per ton | \$6.306 |
| Receipts, including cash, ore, and stock sales..... | 102,287 |
| Expenditure covering every account | 92,363 |
| Cash on hand at end of 1913 | 9,924 |

The superintendent, Nels Nelson, stated that the vein was of no value at 435 ft.; a good deal of work was done at 535 ft., and some ore was extracted; good ore, over 2 to 2½ ft. wide, has been opened at 635 ft.; little work was done at 835 ft. owing to bad ventilation and the distance from the old shaft, there is good ore on this level; No. 2 shaft was sunk to 1200 ft., and stations were cut at 600, 800, 1100, and 1200-ft. levels; cross-cutting is under way at the latter level, and 15 ft. of quartz was cut worth \$3 to \$10 per ton, and this part of the mine is encouraging.

NEVADA CONSOLIDATED COPPER COMPANY

The report for the last quarter of 1913 shows that the output of copper was 16,684,955 lb., and a total of 64,972,829 lb. for the year, against 63,063,261 lb. in 1912. Ore milled during the quarter was 833,989 tons, averaging 1.58% copper. Of this, 93% was from the pits and 7% from underground

OPEN-PIT MINING AT ELY, NEVADA.

workings of the Veteran mine. The cost per pound of copper produced, including all charges but ore exhaustion, was 8.63c. Copper on hand and in transit at the end of the term was 27,916,946 lb. The accounts show the following figures:

| | |
|---|-------------|
| Quarterly revenue | \$1,213,918 |
| Dividend No. 17 of 37½c. per share..... | 749,796 |
| Ore exhaustion | 141,272 |
| Depreciation and income tax | 206,561 |
| Net credit | 116,318 |
| Dividend (extra) of 50c. per share from surplus account | 999,728 |
| Surplus, reduced by extra dividend | 7,971,850 |

THE HYDRAULIC POWER & SMELTING COMPANY

This Company was registered August 4, 1911, to acquire from the Norse Power & Smelting Syndicate, Ltd., and Knut Tillberg: (a) the whole share capital issued of Aktieselskabet Tyssetaldene, a company incorporated under the law of Norway; (b) all the capital issued of the Norsk Elektrisk Metalindustri Aktieselskab, a company incorporated under the law of Norway; (c) all the capital issued of the Trollhättans Elektrothermiska Aktiebolag, a company incorporated under the laws of Sweden. The capital of the Company is £1,000,000,

in 1,000,000 shares of £1 each. It is planned to decrease the capital to £500,000, with the approval of the shareholders, by reducing the nominal value of each share from £1 to 10s. The latest report issued covers the 14 months ended August 31, 1913. The capacity of the zinc refining works at Sundolaken has been increased from 8000 to 10,000 tons per year, and the contract for the sale of the entire production of the works has been made to the end of 1915, at terms enabling satisfactory profits to be made. New zinc-smelting works are being erected and equipped at Trollhättan. When completed, seventeen 1000-hp. and eight 500-hp. furnaces will be installed. However, none of the complex ores for which the works were designed have been available, and the furnaces have been running on the ordinary classes of roasted zinc ores, which do not yet prove to be commercially profitable. Further money for the financing of the zinc smelting was raised by the sale of the Company's water-power interests in Norway to a new company, registered on July 18, 1913, as the Hydraulic Power Company of Scandinavia, Limited.

ASGARD MINING COMPANY, LIMITED

The Company was registered February 16, 1909, to acquire from J. W. Burkitt, the Mount Roundny gold mines and plant, in the communities of Barkowitz, Siboun, Laby, and Zvestoe, Bohemia, formerly the property of the Mount Roundny Gold Mines, Ltd. The report for the period from July 1, 1912, to June 30, 1913, shows that 32,125 tons was milled, yielding 718.40 kg. of amalgam and 6997 oz.; 582 tons of concentrate yielded 1882 oz.; and 15,864 tons of tailing cyanided, gave 243 oz. of fine gold. The total yield was 9122 oz. fine gold. The average working cost was \$4.52 per ton. The ore reserves are estimated at 126,620 tons, the maximum average being \$17.50 at the 250-metre level, and are estimated to contain 52,205 oz. of gold. The receipts for gold and silver, including gold in transit, amounted to £39,307. The credit balance for the year was £9617. Three dividends of 12c. per share have been declared.

PORTLAND GOLD MINING COMPANY

The report of this Company, which operates an important mine and two mills at Cripple Creek and Colorado Springs, Colorado, covers the work done during 1913. The property includes an area of about 130 acres. The mine manager, F. L. Smale, reports that development covered 12,433 ft., of which 8513 ft. was driving and raising on veins or streaks, the remainder being prospecting in barren country. Results of work around No. 1 shaft, especially on the 400-ft. level, were satisfactory, but on No. 2 side, save the 1600-ft. level, development was not promising. At 1600 ft. stoping ground amounting to 1358 lineal feet was opened, 1028 ft. being on No. 1 vein and 330 ft. on an adjacent formation. Stoping widths are from 2 to 23 ft., but the average is 5 ft., with a shipping value of \$35 per ton. Low-grade ore, but probably profitable, was also opened on this level, mostly on No. 1 vein, for a distance of 500 ft. No. 2 shaft was sunk 64 ft., the bottom being in breccia, with small fragments of granite, which may be of local occurrence. No. 1 shaft was sunk 269 ft. in granite, with no indications of fissuring or mineralization. One hundred and ninety feet southeast of No. 1 shaft, at 1500 ft., a vein was cut in the granite area, and associated with it is a phonolite dike on the east, and a basalt dike on the west. At the point of intersection there was a high concentration of gold in the ore, one assay returning 100 oz. per ton. Driving has shown erratic gold content. Further work in depth, it is hoped, will prove profitable ore. The Roosevelt drainage tunnel has resulted in an average reduction of the water-level by 8¾ in. per month. Ore reserves are about the same as at the beginning of the year. It is planned to do 2500 ft. of development on the 1750-ft. level during the current year, when the shaft reaches this point. It will require 8000 to 10,000

ft. of exploration, in addition, to properly open the ground at this depth. Probably 10,000 ft. of work will be done on the upper levels in the known ore zones. Results of the past year may be stated as follows:

| | |
|--|--------------|
| Ore treated at Victor mill, tons | 178,162 |
| Gold recovered | \$402,923 |
| Ore treated at Colorado Springs mill, tons | 53,245 |
| Gold recovered | \$1,380,713 |
| Ore treated to date, tons | 1,767,592 |
| Gross value | \$36,268,797 |
| Profit in 1913 | 604,443 |
| Dividends | 300,000 |
| Dividends to date | 9,457,080 |
| Surplus at January 1, 1914 | 1,767,789 |

GREAT COBAR, LIMITED

This Company operates a large copper property in New South Wales, Australia, which has been a great deal before the mining world lately on account of troubles at the mine, unsatisfactory returns, and dissatisfied shareholders. In the 'Special Correspondence' pages of this journal of January 17, 1914, the whole question was discussed. The general manager, H. C. Bellinger, resigned, and G. C. Klug, of Bewick, Moreing & Co., is now in charge.

Development in the Great Cobar, Cobar Gold, Chesney, and Peak mines covered a total of 8491 ft., and 2164 ft. of diamond-drilling in the parent mine. The main shaft in this mine is down to 1515 ft. The northern orebody was disturbed on No. 10 level, but prospecting has failed to find a profitable shoot. No. 13 level was disappointing. A creep occurred in the southern and central parts of the mine, rendering temporarily unavailable 146,000 tons of ore between No. 5 and 8 levels. The central orebody in the lower levels to No. 14, shows a reduction in size, while ore has not been found in the northern and southern orebodies below No. 11 level. Considerable ore has been developed on No. 3, 4, 5, 6, 7, 8, and 9 levels. Ore reserves are 1,468,749 tons worth 2.49% copper, consisting of basic, silicious, neutral ores, and ore in 'bridges,' also 314,881 tons of ore in upper levels, around the shaft, and broken in stopes. The Cobar gold mine's shaft is down to No. 5 level, and most of the work was done at this depth. Ore reserves are 308,545 tons, assaying 1.7% copper and 0.34 oz. gold per ton. The Chesney shaft is down to 925 ft. No. 8 level development was not promising, and the shaft is being sunk a further 130 ft. Reserves are 612,986 tons, containing 2.58% copper.

The year's results may be summarized as follows:

Smelter work:

| | |
|-------------------------|---------|
| Ore smelted, tons | 361,566 |
| Copper tons | 5,811 |
| Gold, ounces | 27,136 |
| Silver, ounces | 127,542 |

Concentration and flotation work:

| | |
|--|----------|
| Ore concentrated, tons | 50,383 |
| Tailing treated by flotation, tons | 21,810 |
| Jig recovery, per cent | 37.33 |
| Flotation recovery, per cent | 77.53 |
| Combined recovery of copper in ore, per cent | 85.91 |
| Revenue from copper, gold, silver, coal and coke, etc. | £713,206 |
| Expenses at the mines and works | 472,280 |
| Australian taxes | 7,701 |
| London expenses | 10,897 |
| Gross profit | 81,926 |
| Balance from last year | 34,356 |
| Debenture interest | 40,009 |
| Balance for next year | 23,210 |
| Metals in transit, stocks of ore and products, stores. | 203,989 |

The directors of the Company had the properties examined by W. Pellew-Harvey, and his complete report is published in the one under review.

Decisions Relating to Mining

COAL LAND—PURCHASE PRICE

Where a coal land applicant filed a proper application to purchase, complied with the regulations of the Department as to publication of notice, etc., and paid the price of the land as determined by conditions then existent as to distance from a completed railroad, he is entitled to purchase at that price notwithstanding the subsequent completion, prior to allowance of entry, of a railroad within fifteen miles of the tract.

Brown Bear Coal Association, 42 Land Decisions, 320. August 13, 1913.

MINING LEASE—ASSIGNEES LIABILITY

Where a mining lessee, under a lease which would expire in 1928, in 1910 leased the property for 20 years, the lessee, under the lease, was, an assignee of the original lessee, and not a sub-lessee, since, where a lessee parts with his whole interest, there is an assignment of the lease and it is immaterial what kind of an instrument or conveyance is used to dispose of the term. In such a case the assignee is liable to the original lessor for the stipulated royalty.

Pennsylvania Mining Co. v. Bailey (Arkansas), 161 Southwestern, 200. November 24, 1913.

CUTTING TIMBER ON MINING CLAIMS

The rights to the timber on the surface of lands embraced within mining locations as conferred by Section 2322 U. S. Revised Statutes, according to the interpretation placed thereon by the Secretary of the Interior, are limited to the cutting of timber necessary for the development of the mine or incidental to operations related thereto. The land must be actually mineral in character and the location must be made in good faith and not for the purpose of controlling water courses or to obtain valuable timber thereon.

Suggestions, 42 Land Decisions, 310.

ACT OF 1866—RIGHTS OF WAY UNDER, PRESERVED

The incorporation into a forest reserve of land over which prior rights of way for pipe-lines, ditches, and canals have existed does not deprive the possessors of such rights of way of the right to use them nor compel them to obtain permits for the continuance thereof from the Department of Agriculture. Section 9 of the Act of 1866 was not repealed by the Act of March 3, 1891, or the Act of March 3, 1891, or the Act of February 15, 1901, and rights of way taken under the provisions of the earlier act are recognized.

United States v. Utah Power & Light Co. (Utah), 208 Federal, 821. March 31, 1913.

OIL LEASE—PARTIAL CANCELLATION

Where an oil and gas lease provided that a well should be completed on the premises within six months, and the lessee proceeded to drill one well into an upper stratum which produced oil in paying quantities, but thereafter neglected and refused for a period of five years to drill any further wells on the leased tract, although it was proved that the surrounding land contained still another stratum of oil sands at a greater depth, the lessor was entitled to at least a part cancellation of the lease for non-performance of its implied covenant of "reasonable diligence," in order that lessor might prevent her land from being entirely drained of oil through operations on adjoining properties.

Jennings v. Southern Carbon Co. (West Virginia), 80 South-eastern, 368. November 25, 1913.

This publication covers the work done in the state during the fiscal years ended June 30, 1911 and 1912. Included are papers prepared by the members of the staff, under the state geologist, Richard R. Hice, dealing with the different areas of the state, and mineral production for the years given.

HEATON'S ANNUAL, 1914. The commercial handbook of Canada and Boards of Trade register. Edited by Ernest Heaton, J. Beverley Robinson, and W. J. Dobson. P. 442. Index. Published by Heaton's Agency, Toronto. Every country boasts of one or more reliable year books, and this one deals with all topics of interest in Canada at the present time. The editors state that this is the Annual's tenth year, and the publication has been a great success every year. One chapter deals with Canadian towns and the local opportunities offering to anybody desiring to start business in them. Twelve pages are devoted to the mining industry. A multitude of other interesting facts is given.

A Gasoline Mine Locomotive

The Geo. D. Whitcomb Co., of Rochelle, Illinois, has recently appointed Parrott & Co. as agent on the Pacific coast. The Company is already represented at Denver by Hendrie & Bolthoff. The Whitcomb company has been in the mining machinery business for 25 years, and for the past nine years has been specializing on a haulage motor for mining operations, making them in sizes ranging from 3 to 20-ton capacity, and either with or without cabs. The Whitcomb motor has been operating principally in the middle and eastern states, but during the past two years, has been placed in a large number of mines in the West. The Alaska Treadwell Co. has three; the Colorado Fuel & Iron Co., four; the Washington Union Coal Co. and the American Fuel Co. of Utah, each has two large motors, as has also the Union Pacific Coal Co. The manufacturers claim many superior points in the general construction of these motors, but invite especial attention to the following points:

1. A fool proof gasoline supply tank. There are four tanks to each motor. They are made of sheet steel with heavy

WHITCOMB GASOLINE LOCOMOTIVE USED BY THE CALUMET & HECLA.
THE STANDARD UNDERGROUND LOCOMOTIVE HAS NO CAB.

brass fittings, tinned inside and outside after being assembled, then thoroughly tested against leakage. The tanks are thoroughly encased and protected by strong covers and are so constructed that no gasoline can be put in or taken out except through a pipe leading to the engine when they are in the motor. Two tanks are used at a time and cannot be replaced without closing valve in tanks and pipe line. The tanks are refilled outside of the mines and carried in and placed on the motor without danger even in the presence of the miners' lamp. The amount of gas escaping from exhaust or otherwise, is reduced to a minimum and where ventilation is up to the law requirements, there is absolutely no cause for anxiety.

2. The cooling system is a rough and ready one, comprising heavy cast iron tanks of the condenser type, a circulating pump for forcing the water driven from the main shaft and a fan of Sirocco type fitted on the main driving shaft. The fan case is formed to create a split in the air current, half of the air being forced to each side of the motor and through the water into cooling tank.

3. A most interesting feature of the Whitcomb motors is the multiple disc forward and reverse clutch, used in all motors of over 5-ton size. This clutch is made up of highly polished steel discs, alternating with bronze discs, in which latter are inserted over 100 corks one inch in diameter, pressed through a half-inch hole. The corks are finished to 1/32 in. above the surface of the bronze disc. The value of the friction clutch for reverse or forward movement is apparent and this design is a specially efficient one and will stand up to a 50% overload.

The Whitcomb motor is made to operate on distillate oils as well as gasoline. These machines are operating at an elevation as high as 13,000 ft. and upon grades as steep as 15%. The Portland Gold Mining Co. Colorado Springs machine, an 8-ton motor, is hauling an average of 21 tons wet tailing 3000 ft. 4½ to 8% grades on three shifts of 8 hours each and using 7 gal. of oil per shift. This is approximately 9-10 of a cent per ton hour. Many instances show fuel expense as low as ½c. per ton hour.

Safety Winches and Crabs

The Brown Hoisting Machinery Co., of Cleveland, Ohio, is now equipping its standard crabs and winches with Weston patented safety lowering devices. These prevent the handle flying back and ensure the safety of operators. When the load is being raised, the crab automatically locks itself upon the handles being released. Lowering is accomplished by simply turning the handles backward. The lowering ceases when the cranks are released. The Weston device is described in Pamphlet C, 1914, as follows:

THE WESTON DEVICE.

A sectional view of this safety device is shown in the figure and its operation can be easily seen from this view. It is placed on the main crank shaft and consists of the driving pinion which operates the drum gear, and a pawl and ratchet. The driving pinion and the ratchet are loose on the shaft. They are separated by the metal discs B and C, which are placed alternately. The discs B operate with the ratchet and the discs C operate with the driving pinion, so that when the driving pinion turns in the ratchet, there is a frictional resistance between the discs, the amount depending upon the lateral pressure. The ratchet and the pinion are held between the two fixed collars A and D. The collar A and the driving pinion have helical bearing faces which when turned one on the other, act as a screw on the driving pinion. When the hand crank is turned in the hoisting direction, the screw action between the helical surfaces presses the driving pinion and the ratchet against the discs B and C. The friction between these discs is so great that the driving pinion and the ratchet are locked together and they rotate with the shaft, thereby hoisting the load. The friction between these discs prevents the load from running down. When the load is suspended, it is held by the pawl engaging with the ratchet. To lower the load, it is necessary to turn the cranks backward with only enough force to overcome this friction. But the load can lower only just as fast as the cranks are turned, because any greater speed is prevented by the driving pinion locking with the ratchet. The ratchet can turn in only the one direction on account of the pawl, and that is when the load is being raised. When the cranks are released the driving pinion is immediately locked between the fixed collar A and the ratchet. The metal discs are lubricated and the lowering is accomplished smoothly and not by jerks, which saves in the wear on the machine and also on the hoist line.

F. A. BELT of Mt. Washington, Ohio, has issued a brief circular describing his new duplex calculator, a simple machine for multiplying, dividing, calculating cube and square roots, getting fractions, percentages, and making simple conversions.

EDITORIAL

LACK of space incident to our printing full particulars of the New York meeting of the Institute has crowded out a number of interesting and important matters that must needs be deferred.

ARGUMENT before the Circuit Court of Appeals at San Francisco, last week, of the case of Minerals Separation against Mr. James Hyde and his associates for infringement of patent rights, brought together a number of men famous in connection with flotation and served to make public much interesting historical and technical data. While it would be improper, pending decision of the case, to discuss its merits, we expect to present shortly a summary of the chief arguments advanced by each party to the controversy.

The Institute and Mining Law Revision

The meeting of the American Institute of Mining Engineers that was held in New York last week was especially notable in two particulars. In the first place it marked the close of a year's work of the Institute under the new constitution and on the new basis. In the second, the position of the Institute as an authoritative adviser of the United States government in matters relating to mining was definitely recognized. Both events are worthy of comment.

A year ago the Institute was working under a system which by custom as much as by terms had come to mean closely centralized authority. Election of officers was a formality, and at the annual business meeting seven members constituted a quorum. To the membership in general the Institute had become merely a publishing house and was known by its *Transactions* rather than its deeds. The *Transactions*, it was conceded, were superb, as they were bound to be under the management of an exceptionally able and devoted editor. But the average member of the Institute thought of it as an outside organization in which he had no personal part; just as the majority of the wealthier Mexicans today look upon the troubles of that unhappy country as a concern of the Government, not of theirs. In the Institute, fortunately, a new spirit stirred and the time came when the membership at large was willing to go to work. As always in such a crisis, leaders appeared and, without making invidious comparisons, it may be fairly stated that among these, the retiring president, Mr. C. F. Rand,

proved the most important. The Institute owes much to many men and to Messrs. C. R. Corning, A. R. Ledoux, James Douglas, Phillip N. Moore, and others who contributed of their time, courage, and patience in the troublesome weeks of 1912, there is a heavy debt; but to Mr. Rand it fell to be the actual leader through the year of reconstruction. With characteristic modesty he has given all the credit to others, but those who have kept in touch with the situation know that it was the quiet unselfish man in the president's office who did most of the work. The achievements of the year have been summed up in the statement that he converted a mob into a disciplined army. Certainly the organization of the members into a series of technical committees is proving an effective means of increasing their activities. We need accept neither the optimistic beliefs of those who see in this a permanent cure for all evils, nor the doleful predictions of those who refer to the rapid decay of new brooms, to credit the move with much usefulness and many possibilities. When the committees become moribund, if they do, another and possibly a better method of provoking discussion and registering public opinion may be put in operation. The Mining and Metallurgical Society has one such method and it has accomplished results of note. The committees in themselves are unimportant, but the fact that a considerable portion of the membership of the Institute has been awakened and set to work, is profoundly significant.

Among the new technical committees, that on mining law, under the able chairmanship of Mr. Horace V. Winchell, easily attracted chief attention at the New York meeting. We listed last week the papers on this subject that were to be read, and we print this week notes on the actual sessions. The keynote of the meeting was the necessity for revision of the mining law. Mr. Winchell presented the case for the plaintiff in a carefully prepared statement of reasons why the law needed thorough reconstruction. Briefly these are: (1) that the law was not planned to apply to many kinds of mineral deposits or to conditions as they are today; (2) that it discourages prospecting; (3) that the apex or extralateral right provokes needless litigation; (4) that it contains no provision for court review of land office decisions; (5) that the coal land and oil land laws are inadequate and antiquated; (6) that no suitable provision is made for lands containing radium-bearing minerals, potash salts, phosphates, and other minor products; (7) that no notice of mining claims is required by the United States; (8) that there is no statute of limitations as to attack on patent for placers on the basis of irregularity or fraud; (9) that an unlimited number of quartz claims may be located by one individual. There is not room here to detail Mr. Winchell's excellent arguments in support of these criticisms, but we print on other pages the paper by Mr. C. W. Goodale, in which is presented the details of one case illustrating excellently the actual results of our law of extralateral rights.

A definite plan of procedure looking toward the

needed modification of the mining law has been worked out by Mr. Edmund Kirby as chairman of the committee on mining law revision of the American Mining Congress, and was presented at the Institute meeting. Congress has been asked to create a commission to hold hearings in the mining states and to prepare and present, not later than next January, a definite bill for a new act. In the address delivered by Mr. Thomas J. Walsh, senator from Montana and chairman of the Senate Committee on Mines and Mining, which we print, the present status of this and other legislation is discussed. It is evident that rapid and sure progress is being made. We regret the apparent purpose to constitute the proposed commission wholly of lawyers. They should be represented, and it goes without saying that no statute should be loosely or carelessly drawn. It should not only be written in well chosen words, but it must be constructed with full knowledge of existing laws, customs, and court decisions. It is neither wise to go on indefinitely patching the old law nor to sweep it aside entirely. Our laws are like our institutions. They grow out of our needs and our life, and are not to be lightly changed. All this may be conceded and yet it may be fairly demanded that the mining men be represented on the commission. They are the ones chiefly concerned and they should at least be given the opportunity to formulate and present their ideas in finished form. It is as pertinent to suggest that the lawyers appear before the commission as that the mining men do so. It is hardly likely that any bill drafted by this commission will be accepted without change, and on both the Senate and House Committees are excellent lawyers well informed as to mining. They will have the final word as to the form into which the proposed law shall be cast. If to the chairmen of the two committees three others nominated by the President should be added, with the understanding that all should be familiar with mining, and one or more should be a trained lawyer, an excellent body would be created.

There is one other, though minor point, in Mr. Walsh's address to which we take exception. Though among those who have favored the adoption of the leasing system, we have been careful time and again to point out that this is a matter of policy concerning which there is abundant room for difference of honest opinion, and while we deplore as sincerely as does Mr. Walsh, the intemperance that has at times characterized the discussion, we have not noticed, while dodging perhaps our not unfair share of brickbats, that it was wholly one sided. The essential thing is that the way now seems opening to agreement on a plan of action. The new law is unlikely to be exactly what any one of us wants, but we can well concede minor points in approval of the intelligent and sympathetic manner in which Mr. Walsh and his associates in the Senate, and Mr. Foster and his fellow members in the House Committee on Mines and Mining, are approaching the problems of the miners. The era of talk seems at last to have given way to one of constructive action.

New York Meeting, American Institute of Mining Engineers

EDITORIAL CORRESPONDENCE

The annual meeting of the American Institute of Mining Engineers was held at the Institute headquarters, in New York, February 16 to 20. The general arrangements for the meeting were made by the executive committee of the New York section, of which L. D. Huntoon is chairman. The opening session was held at 8:30 o'clock on the evening of February 16, and, in spite of the stormy weather, a large attendance was present; a happy augury for the success of the following sessions. A. L. Ledoux was the chairman for the evening and introduced the retiring president, C. F. Rand, with the following remarks:

"In 1910 I met for the first time Charles F. Rand, who had been elected a director of this Institute. He immediately made a strong impression upon me. Quiet in demeanor, with a low voice, he spoke but little, but every time exactly to the point. His suggestions were recognized as pertinent, and his propositions were clear-sighted and met with almost unanimous approval. He had a genius for figures and showed unusual ability for organization. It was but natural that he should be made a member of the finance committee, and thereafter our budgets became more practical. We had had a strong council and board of directors, and most conscientious presidents, but we were all bound by traditions of conservatism which required a shock from the outside to loosen. And the shock came! Later, in 1912, in the stormy days through which our ship was passing, Mr. Rand became, naturally, by unanimous approval, sole nominee for president of the Institute. Not only was he recognized as a proper commander, but he had the rare ability of making us all work with more enthusiasm in our several offices. Early in the year of his presidency, 1913, he commenced to promote local enthusiasm, and the result was a marked revival in the activities of all local sections and the formation of new ones where previously interest in the Institute had waned, in some cases reaching a point where there was danger that new organizations might take some from our membership, whose interest in special branches had led them to believe that these interests could be best promoted outside of the Institute; there was great danger that there would be formed a Pacific Coast association of engineers whose members would secede from us; that the iron and steel men would drift away, as well as those interested in coal, petroleum, etc. This danger was offset not only by the promotion of local sections, but by the formation of many technical committees. It was thought by many, and said by some, with a shake of the head, that the enthusiasm inspired by our president would wane; that the committees would cease their activities sooner or later, and that conditions would drift back to what they were previously. Everybody is

happy to observe how mistaken was this view. The inspiration of the initiative shows no signs of diminution, as is evidenced by the number of papers which these committees have been able to secure for our present meeting. So many, indeed, are they, and so varied, that for the first time, if my recollection serves me, we are to meet simultaneously in different rooms where members may foregather with others especially interested in special lines.

"It is not necessary to speak of the success of the Butte meeting, which was perhaps the most valuable, technically and socially, of any that has been held in recent years, and it may be said that the enthusiasm not to fall below the standard of Butte is forecasted in the arrangements which are being made for our meeting next summer at Salt Lake City. In saying this, I would not detract in the least from the infinite pains taken by the local committee at Butte, nor from the local efforts which are already inaugurated to maintain that standard at our Salt Lake meeting, but would merely emphasize the fact that enthusiasm is not always spontaneous, but results from the example and initiative of some one individual, and the individual in our case is Charles F. Rand.

"Mr. Rand is modest and would be the first, though perhaps the only one, to disagree with me in this estimate, and would say that the success is due to the coöperation which he has had from everyone. I would not detract from the appreciation due to the board of directors, nor to the secretary, but call you to witness if it be not true that the captain of a great ship, who has brought the vessel through great peril safely, should deservedly receive the acclaim, although he may modestly point to the loyal backing and efficient service of all of his subordinates from the stokehold to the bridge. Mr. Rand was not satisfied to leave the presidency with everything working well to insure our future, but desired to increase our membership materially. As the result of his personal efforts, again ably seconded by loyal lieutenants, there has been the greatest increase in membership in any year of our history, no less than 786 applications having been received since February 1913. Not the least of Mr. Rand's services has been in persuading a very busy man to consent to become his successor in the presidency. I am not charged with the duty, and this is not the moment, to say anything about Mr. Thayer; however, I trust that I have reminded you sufficiently of our obligations to Mr. Rand, who will now address you, so that you will feel that what is in the thought of everyone here has had at least some expression, however inadequate."

With characteristic modesty, Mr. Rand, in responding, made only a few brief remarks to the effect that nothing serious was to be done at the opening session,

and that the statements of the chairman should be taken in that spirit. The chairman then announced that certain communications had to be brought to the attention of the members present, and a colored slide was thrown on the screen, showing C. F. Rand being wafted to regions of bliss, attended by angels, while on the horizon the rising sun showed the genial countenance of Mr. B. B. Thayer. Next followed a letter from P. F. Corrigan, consulting miner, of Butte, commending Mr. Rand in his effective work for the Institute, but warning him to beware of getting "too manny collidge profissors" into it, and especially commending his wisdom in securing B. B. Thayer, a practical miner and "a fine feller," for his successor. This was followed by an exhibition of colored slides made from photographs made by the field staff of the Underwood Company showing a great variety of unusual and difficult subjects to photograph, such as mountain peaks, volcanic explosions, battles in recent wars, and so on, in which great interest was displayed by all.

The regular meeting began with the business session at 10 o'clock on the morning of February 17. The usual reports of the officers and standing committees were read and approved, and A. S. Dwight and E. G. Spilsbury, acting as tellers, announced the results of the letter-ballots for officers.

The number of ballots received was 941, and the following gentlemen, having received the respective number of ballots set opposite their names, were declared elected: President, B. B. Thayer, 934; vice-presidents, H. C. Hoover, 925, W. L. Saunders, 903; directors, C. W. Merrill, 925; A. L. Ledoux, 924; R. W. Brock, 917; H. L. Smyth, 916; D. C. Jackling, 876. The president then announced that Dr. James Douglas, who undertook last year to raise the funds to cancel the land debt of the Institute, had turned over to the treasurer \$28,000 in cash, and pledges of members aggregating \$6000 more, which would cancel the unpaid balance of \$34,000 remaining on the land debt, thus relieving the Institute of the burden of nearly \$3000 per year for interest charges. The gift was accepted with thanks for the effective service Dr. Douglas had rendered in raising the sum. Mr. Ledoux gave notice of his intention to propose an amendment to the constitution providing that members should not be dropped for non-payment of dues until they are two years in arrears. E. W. Parker and J. W. Richards were appointed a committee to draft a tentative form of amendment, which was presented later in the morning and discussed at some length. This amendment cannot be acted upon until the next annual meeting, but at the suggestion of A. C. Lane, a vote was taken upon it in order to indicate to the board of directors what the sentiment of the membership is. The vote disclosed a large majority in favor of a more lenient provision than that in the new constitution adopted last year.

The business session was then adjourned at the call of the president, and the reading of technical papers was begun. In the absence of H. A. Guess, his ad-

mirable paper was presented in abstract by B. A. Robinson and was well received. But, as is usually the case, the absence of the author put a damper upon the discussion. The same was true of the following paper upon metallurgical practice at the Nipissing mine, by James Johnston, though R. E. Hore and others called attention to some of the more important features of the paper. Adjournment was then taken for lunch, which was served in the adjoining room, and the members spent a pleasant hour in foregathering, the cordiality of the gathering being stimulated by a committee of members of the Institute appointed for the purpose.

At the afternoon session on Tuesday, William Kelly presided. The first paper, by H. H. Clark of the Bureau of Mines, was on safeguarding the use of electricity in mines. This was followed by another paper on the same subject by C. M. Means, of the Pennsylvania State Bureau of Mines, which was read in abstract by the chairman, in the absence of the author. The two papers were then discussed together by G. S. Rice, B. F. Tillson, and others, the discussing coming to centre about the use of portable electric lamps and their constructions. This was followed by a discussion of the use of electric motors and shovels for excavating purposes, by H. W. Rogers. This was discussed by E. G. Spilsbury and also by F. H. Armstrong, who described a recently constructed shovel in which water is pumped into an accumulator by an electric pump, the mechanism of the shovel being actuated by the water. This has not yet been put into operation. This paper was followed by one on electric mine locomotives and coal-cutting machines, by A. W. Belden. Another paper on electric haulage underground, by Charles Legrand, was passed over, in the absence of the author. The use of electric energy for hoisting, milling, and electric concentration at the Mineville iron mines was discussed by Solomon Le Fevre. This was followed by an account of the use of electricity at the Penn and Republic mines of Michigan, by William Kelly and F. H. Armstrong. The session was concluded by an account of the records made in drilling work during the construction of the Kensico dam, of the Catskill aqueduct system, by W. L. Saunders.

The evening session was held at the American Museum of Natural History, and was opened by a lecture on hydraulic mining, by Howard W. DuBois, illustrated by numerous colored lantern slides and a moving picture of hydraulic operations. Following this, E. O. Hovey gave an illustrated description of the Copper Queen mine, and then an opportunity was afforded for those present to inspect the model of the Copper Queen mine, as well as the model of one of the stopes, which has been presented to the Museum by Dr. Douglas. These have not yet been placed on view to the public, so that the evening was therefore a private exhibition for the benefit of the members of the A. I. M. E.

Mining Legislation at Washington

By THOMAS J. WALSH

*The Committee on Mines and Mining of either House of Congress has not heretofore been regarded as much more than one of the numerous paper committees, created and preserved chiefly to afford to the representative designated as its chairman, a needed clerk. It bids fair at present, however, more because of the important legislation affecting the mining industry that crowds upon the attention of Congress than by reason of the personnel of its membership, to be transformed from a more or less moribund organization to an active legislative force. The haste in which this résumé is necessarily prepared impels me to confine my remarks to measures that have been referred or which it is expected will be referred to the Senate Committee.

The Revision Commission Bill

This has had under consideration a bill introduced by Senator Smoot, for the creation of a commission, charged with the duty of revising and modifying the laws in relation to the appropriation and occupation of mineral lands of all kinds, a subject which, as I am advised, has had repeated consideration by this body. As the bill came to the committee the commission was to consist of three members, one of whom should be a lawyer of experience in the practice of mining law, one a mining operator, and one an officer of the Geological Survey. Being referred to the Department of the Interior for an expression of its views, it was proposed that the membership be increased to five, giving the Bureau of Mines a representative and an additional representative to the operator. It was, however, urged before the committee that as the work devolving on the commission is the preparation of a draft of a code of laws, that in the past have given rise to interminable litigation and that are likely to be a fruitful source of perplexity to the courts for years to come, it ought to be entrusted exclusively to lawyers of eminence and character, conversant with the troubles that have been encountered in the past, and most competent from this experience and learning to devise a system under which unnecessary controversies may be avoided in the future. While the suggestion might appear to have originated in a desire upon the part of members to take care of their brothers of the law, a little reflection will exhibit much merit in it. It was advanced that the commission being authorized to hold public hearings throughout the mining regions affected, and elsewhere, at will, it would unquestionably invite an expression of views from operators, engineers, and prospectors, from representatives of the Geological

Survey and the Bureau of Mines. The bill contemplates that a report shall be made before January 1, 1915, and provides that each member of the commission shall be paid a salary of \$500 per month for the time actually devoted to the work.

It is now over forty years since our system of laws in relation to the disposition of mining lands was devised. Generally speaking, it has met the conditions in a most satisfactory way, excepting always, the part dealing with the disposition of lands containing coal. That part never would have been operative at all had not the practice now condemned as criminal been pursued. As the appropriation of coal lands has all but ceased in consequence of the failure of the law to recognize that an entry of 320 acres will not justify the expenditure necessary to the mining of coal on a commercial basis, a revision in respect to lands valuable for coal is imperative. Aside from that feature, however, the conviction is quite general that the extralateral rights give rise to complications so numerous and serious, it is such a prolific breeder of litigation, not infrequently characterized by imposition and perjury, that it ought to be abandoned. The idea in which it had its origin was a just purpose to stimulate the prospector by assuring him the vein discovered through his sagacity and his self-denial, and was most commendable. But in practice it often served to deprive the enterprising miner of the legitimate fruit of his toil and expenditures. Every lawyer of experience is familiar with instances in which orebodies of great value have been uncovered by expensive development made by the owner of the claims in which they are found, and who has been obliged to yield them up upon the claim of an apex in adjacent territories, the owners of which had no suspicion of their existence.

It will be found profitable to compare the working of the system to which we have become attached, with those that have been developed during the past two score years in the English colonies, the Latin-American republics, and other nations that have been required to legislate concerning the public mineral lands. An enlightened public sentiment concerning our mineral land policies can be formed only in the light that is afforded by knowledge of the kindred systems of the progressive peoples of the earth. A compilation of such laws, accompanied by a brief explanation of their character and the measure of success which has attended their working, is all but essential to comprehend the actual value of our own.

The Alaska Coal Land Bill

Some of the questions with which the commission will be called upon to deal, should one be appointed, brook no delay. They must be met at once and solved

*Address delivered before the American Institute of Mining Engineers at New York by the chairman of the Senate Committee on Mines and Mining.

in some way looking to revision later in the light of facts brought out or views advanced by those deputed to study the subjects as a whole. Of this character is the question of how to open the Alaska coal deposits.

The bill providing for the construction by the Government of railroads in that territory from the seaboard to the inland waterways, has passed the Senate and will speedily, it is believed, be approved by the House. The President's sanction of the general purpose of this act has been given in advance in his message to Congress. It must be accompanied by an act which will permit and invite the workings of the coalfields. It is idle to imagine that the Executive Department will advance one step toward the construction of railroads in Alaska unless assured in advance that coal mines will be opened to afford fuel during construction and traffic when the road is built. The Senate Committee has under consideration a bill which is the result of repeated conferences participated in by the Secretary of the Interior and his staff and the chairman of the House and the Senate Committees respectively on Public Lands, Territories, and Mines. It is a frank adoption of the leasing system, to which none of those having any conspicuous part in the preparation of the bill confess any attachment. The Congressional members are all convinced, however, that the concession is essential to the necessities of the case. They entertain the view that to enact a law providing in any terms for the disposition in fee of coal lands in Alaska would be in effect to doom the country to another decade of inaction. I am myself of the opinion that any Secretary of the Interior who should permit Alaska coal lands to be patented under any kind of a law passing the fee would be driven from public life, and it would be good fortune if he did not pull down the temple of the administration of which he formed a part as he passed out of it. It is to be regretted that a great public question such as this is cannot be debated dispassionately and without impugning the motives of those who adhere to what may be said to be the Western view, except when and insofar as the conditions point to selfishness in those upholding it. The promoters of the leasing plan never admit the possibility of an honest difference of opinion concerning the wisdom of the departure they propose. All who oppose them are involved invariably in the common denunciation which is leveled at the plunderers of the public domain and the defenders and apologists for such. There has been no deliberate judgment by the American people in this supremely important question. They have been turned by invective from the consideration of it. The leasing system was tried in connection with the lead lands of the Mississippi Valley and abandoned after proving a dismal failure. Probably the essential difference in the conditions under which it was tried and those now prevailing deprive the experience we had under it of anything like controlling force, but if so the public has not been advised as to why the same troubles are not in store for us. Calumniation has been so long the portion of those who have sought to gain a fair hearing

for the system of alienation of fees that few remain who have not despaired of securing considerate attention to the merits of that plan. Anyway the friends of Alaska are without hope of convincing the public mind, at least not speedily, that as to coal deposits, popularly believed, and doubtless with justice, to be exceptionally rich, the leasing system is not a most doubtful experiment. The people of Alaska pray for any kind of a law which will permit them to mine coal. They have ceased to debate the merits of rival systems.

It must be confessed that the plan of reserving title in the government is growing in favor. The Western representatives are much more tolerant of this idea than they once were. The legislation of such states as Colorado and Montana concerning their own coal lands, forbidding their sale, but authorizing the operation of them under leases, is appealed to with embarrassing effect. It is true that the policy of the state is primarily to make as much money as it can out of its school lands while the policy of the federal Government is, or ought to be, to make its lands serviceable in the development of the sections in which they are situated. But the state is not altogether unmindful of its larger interests in the sale of its granted lands, and the policy of local development is as well subserved under a leasing system, if all the returns are devoted to improvements within the state, instead of going to meet the general demands upon the federal treasury. The Northern Pacific Railway Co. has the most vital concern in the rapid development of the territory adjacent and tributary to its lines. But it has also adopted the leasing system as to its coal lands and declines to sell such at any price.

Those responsible for the Alaska coal land bill referred to, find sufficient justification in the foregoing to tender a measure recognizing the leasing system. Under it the Secretary of the Interior is authorized to withdraw eight sections in the Bering River coalfields and twelve sections in the Matanuska field for the use of the navy or to be used in connection with the government construction work or for disposition by Congress in case of oppressive conditions arising from monopoly, it being contemplated that the Government might in the future deem it the best solution of difficulties which might arise similar to those encountered in connection with the anthracite coal situation in the east, itself to supply the market from its own fields. Leases are authorized for indeterminate periods with provisions for readjustment of prices every 20 years, no lease to be for more than 2560 acres to any person or corporation. Drastic provisions are inserted in the law to prevent evasion of the provision limiting the area in which any individual may be interested. Forfeiture and imprisonment are the result of conviction. It is believed the risks are so great that few will care to take the chances involved in an effort at monopoly. The royalty is fixed by the lease but cannot be less than two cents per ton, and it all goes toward the redemption of the bonds issued for the construction of railroads in the territory and for purposes of similar character when

the obligation created by them is discharged. The lessee is entitled to sue the Government on any cause of action arising out of his lease in the Courts of Alaska, so that any arbitrary or destructive policy on the part of the Department may be restrained and questions arising upon the construction of the lease determined as they would be between private parties under like circumstances. To compel the operation of any ground leased, a rental in addition to this royalty is exacted at the rate of 25c. per acre the first year, 50c. per acre annually for the next four years, and \$1 per acre for each year thereafter. For local use the Secretary is authorized to issue permits without any charge for the working of tracts not to exceed ten acres, the purpose being to permit the homesteader and miner to secure coal for his own use at an adjacent bed.

The Radium Bill

A third bill before the Committee which has given rise to much discussion appertains to lands containing a radium-bearing ore. These are mainly pitchblende and carnotite. The former is often, perhaps usually, found in metal-bearing veins and in association with the precious metals as well as with zinc and lead, the latter, so far as known, appears only in veins or pockets in sedimentary rocks. The carnotite ores are the chief source of supply. They abound in an area reaching from Colorado into Utah, 150 miles long and varying in width from 5 to 25 miles. Discoveries have been reported in Arizona, Montana, Idaho, and South Dakota, but no authentic information is available of any workable fields save those of Utah and Colorado. The wonderful advance made in the use of this remarkable agency in the eradication and cure of cancer and other malignant growths has directed the attention of the world to the sources of its supply. The exceptional riches of our western fields have made the output of them eagerly sought after by the laboratories and reduction works of Europe. Two great plants in the state of Pennsylvania are now treating the ores and claim to be supplying the trade each with a gram a month salable at about \$120,000. Thus far their production has gone very largely to foreign markets, as has practically all the ore not treated by them. They own the claims from which their supply is drawn, one of the companies having acquired about 140 claims. Another association has 80 odd, a third 40 or more. Though the crude ore which is the source of by far the greater part of the products of the works in Europe comes from this country, our surgeons are forced to go there to procure their supply. Unmistakable evidence is at hand of something like a race to purchase or locate every deposit of any prominence, and surgeons of eminence who are intensely interested in the success that has been achieved in the use in therapeutics of this singular substance, and the still more marvelous possibilities that experiments are constantly revealing, became genuinely alarmed on visiting the region from which the ore comes lest the whole of it should speed-

ily fall into the hands of a monopoly which might maintain the price of its product so high as to make it available for the treatment of those only who could afford to pay anything that might be demanded.

These conditions prompted the introduction of a bill which obligates the locators of all claims containing radium-bearing ores to sell their products to the United States at the market price to be fixed by the Secretary of the Interior. Development work or mining during a period or for periods aggregating four months is required, and even after patent, if the property is not worked with diligence, the Secretary is authorized to enter upon the property and mine it, paying to the owner the market value of the ore, less the cost of extraction. Rights to claims located prior to the passage of the act are, of course, not affected, but the Government is given the preference right to buy the output of all claims hereafter located. The Bureau of Mines is perfecting a process which it is claimed will enable it to reduce the ores at a cost not to exceed that now attending similar work by private companies. Two questions are of first importance in the consideration of this measure; first, whether it is justifiable to impound all ores produced in our territory to supply the needs of our people; and, second, whether the peril of monopoly is sufficiently imminent to justify the Government in itself undertaking the work of extraction.

Non-Metallic Minerals

Various other bills related in character to those referred to will be considered in conference, such as have been mentioned, and then introduced. First in importance is an oil and gas bill. The basic feature of this bill is one which permits the discoverer to purchase a limited portion of a tract for the exploration of which an exclusive license is issued to him, the remainder then being leased. It is proposed to give the adventurer the exclusive right for two years to prospect over four sections, if they are distant 100 miles from a producing well, and over one section if it is less. Should he discover oil or gas, he is entitled to locate, in the one case 640 acres, in the other 160 acres of the land included in his permit, acquiring title under the procedure described in the case of placer mines.

The same principle is to be made applicable to the disposition of valuable deposits of chlorides, sulphates, borates, or nitrates of potassium or sodium. Phosphate deposits it is proposed shall be leased in tracts not to exceed 320 acres by competitive bidding. The royalties from all leases of lands outside of Alaska, except so much as is deemed necessary to defray the cost of administering the laws (for this principle applies to all leasing measures) go into the reclamation fund. A general coal land bill has been prepared by the Department on the same lines. The Committee of both Houses, the Department, and the Congress will be thankful for any consideration you may give these various measures and for any helpful suggestions.

The Apex Law in the Drumlummon Controversy

By CHARLES W. GOODALE

The litigation between the St. Louis Mining & Milling Co. and the Montana Mining Co., Ltd., over portions of the Drumlummon lode covered a period of more than 20 years, and resulted in a judgment for damages in favor of the St. Louis company of such an amount that the Montana company declined to pay the judgment and therefore lost the entire property.

The Drumlummon lode claim, in the Marysville district, Montana, was located in 1876 by Thomas Cruse,

advisable to acquire adjoining claims on both sides of the Drumlummon, in order to avoid possible litigation over apex rights. They bought the Marble Heart, but would not purchase the Hopeful at the terms proposed for the reason that exploration in the Cruse level had shown the vein to be barren in that region. The owners of the Hopeful were sinking a shaft on that claim in 1889, and the Montana company enjoined them, contending that, owing to the triangular form of the location, it had no extralateral rights. When the cause was heard by Judge Knowles in the United States District Court in Helena, in June 1890, he supported the contention of the plaintiff, and no appeal was taken, because it was found that the portion of the Drumlummon vein in controversy was not of sufficient value to justify further litigation.

The St. Louis claim was located September 28, 1878, as an extension of the Drumlummon. There is abundant evidence from the location notice, and from other facts, that its side-lines were straight, as shown by dotted lines in Fig. 2, but the discovery vein of the St. Louis proved disappointing when opened, and in the meantime the 9-Hour location having been made by William Robinson, July 26, 1880, on a promising discovery of ore, the St. Louis owners, in surveying their claim for patent in July 1881, ran their lines so as to take in the 9-Hour discovery. When Robinson objected, they made angles in their side-lines, leaving out the shaft, but by such a narrow margin (about 10 ft.) that when they applied for patent he put in an adverse claim. On March 7, 1884, he was induced to withdraw his suit, the St. Louis owners agreeing, on the issuance of their patent, to convey him a portion of the ground, known

thereafter as the compromise strip. As this would have the effect of moving the St. Louis line 40 ft. farther away from his discovery, he felt secure in his mineral rights to the 9-Hour vein. The locator had only developed the property to a limited extent, when he sold it to the Montana company.

Going back now to the beginning of the litigation with the St. Louis M. & M. Co., a suit was started on October 14, 1890, by that company against the Montana company for \$2,000,000. An incline shaft had been sunk on the St. Louis claim to a depth of about 370 ft. (Fig. 2) in an effort to find the Montana com-

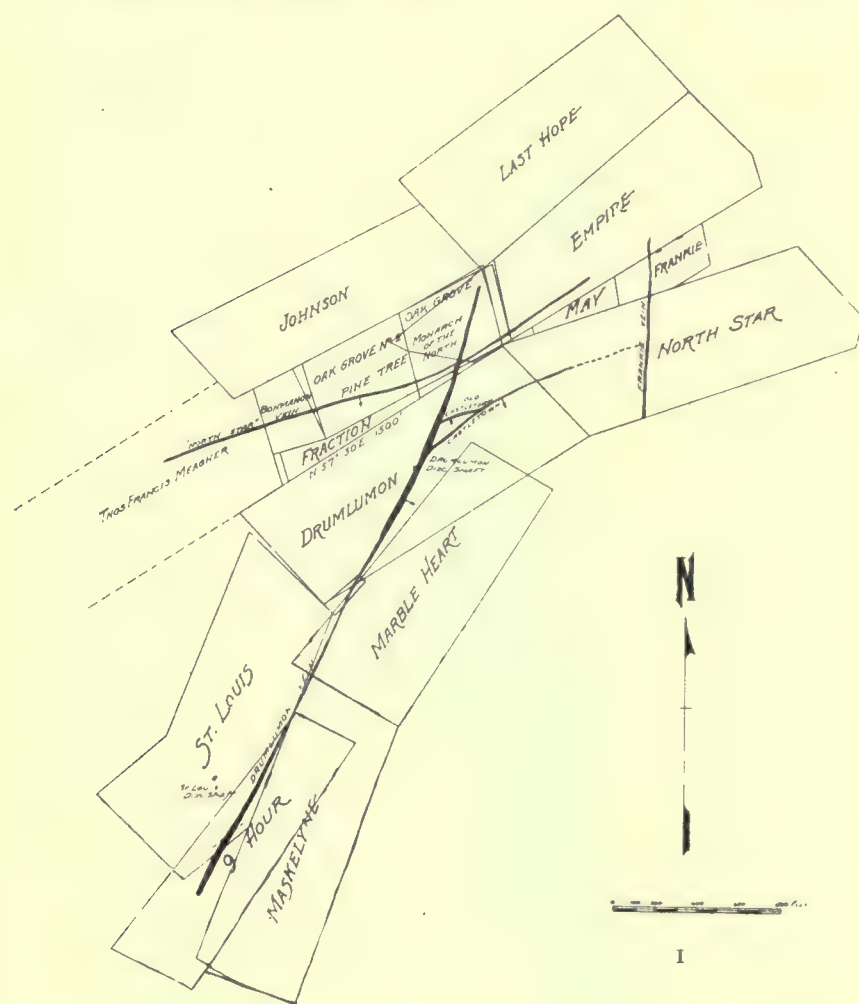

FIG. 1.

When he staked out his claim, he assumed that the discovery on the Drumlummon vein, and another showing of mineral about 200 ft. distant, were on the same vein, and the centre line of the claim was given a course of N. $57\frac{1}{2}^{\circ}$ E. (Fig. 1.) Development of the Drumlummon vein soon showed that its strike was about N. 15° E., and that the other outcrop was on the North Star lode, so it was inevitable that the Drumlummon vein would cross one or both side-lines of the location, and the Montana company found it

*Abstract of paper read before the Butte section and the annual meeting of the American Institute of Mining Engineers.

pany's workings, as it was known that the Cruse level had been driven several hundred feet south of the Drumlummon end-line and into the Marble Heart claim. This shaft was started as close as possible to the side-line of the St. Louis, and was given an inclination parallel to the known dip of the Drumlummon vein. The geologists of the plaintiff asserted that the shaft was sunk on the foot-wall of the Drumlummon vein, and set up the theory that the Drumlummon vein entered their claim at its north end-line with a width of about 70 ft., varying from that to about 30 ft. in its course southerly, and claimed the Jubilee and Jubilee No. 2 ore-shoots in virtue of apex rights to which they were entitled by the alleged fact that they had the foot-wall in the St. Louis claim, the hanging wall being in a junior location, the Marble Heart. The case came up for trial April 17, 1893, in the United States District Court at Helena, and at the conclusion, five weeks later, the jury gave a verdict in favor of the defendant, thus supporting its geologists in their statement that the Drumlummon in its apex through the region in question was a narrow vein, not to exceed 3 ft. in width, existing between two well defined walls, and with a distinctive barren filling. The nature of this vein-matter as shown by analysis of the country slate or hornstone, both within the wide vein as claimed by the plaintiff's geologists and outside of it, showed little difference in the composition, but the plaintiff insisted that what the defendant called the whole vein was only the hanging wall gouge, and that the rock between this and the plaintiff's alleged foot-wall, from 30 to 70 ft. distant, was "broken, brecciated, recemented vein matter." The defendant pointed to many places where the stratification planes of the slate were strongly in evidence, and asserted that wherever they were indistinct this condition could be explained by the proximity to the contact with the diorite.

After the purchase of the 9 Hour claim the Montana company began active exploration of the ground, both at the surface in the discovery shaft and in deep levels. By the summer of 1893 developments had shown that the vein would cross the east side-line of the St. Louis claim as patented, and on June 19, 1893, the St. Louis company commenced an action to restrain the Montana company from working any part of the vein the apex of which was in the St. Louis claim as patented, and for damages, placed at the sum of \$10,000, for ore extracted from within the boundaries of the compro-

mise ground. A temporary order was issued, restraining the Montana company from sinking its Apex shaft upon the compromise ground near the boundary line between this ground and the 9-Hour claim. The case was removed to the federal court, and on September 16, 1893, a new complaint was filed in which the damages were placed at the sum of \$200,000 for the ore then extracted. For a distance of 100 ft. or more at

FIG. 2

the surface, and to a depth of about 50 ft., the ore was richer than had been found in any other workings of the Drumlummon vein, and the fight for its possession became very bitter. The Montana company claimed the right to the ground in controversy by virtue of the agreement to convey the compromise ground. It could not maintain its right without the full legal title to the ground, and thereupon it commenced an action to compel the St. Louis company to deed to it the compromise ground in accordance with the agree-

ment which had been entered into with Robinson and his associates. Pending the proceedings in this 'specific performance suit,' the proceedings in the court were suspended. The suit dragged its length along until the year 1898, when the Supreme Court of the United States affirmed the decision of the State, District, and Supreme courts requiring the St. Louis company to convey the compromise ground in accordance with its agreement, which was done, and a deed was executed July 1, 1898. The patent of the St. Louis claim was issued in July 1887, and William Robinson, or his successor in interest, the Montana company, should have received a deed promptly, but it was only given after eleven years of annoying and expensive litigation.

Amended Complaint Filed

In November 1898 the St. Louis company filed its first amended complaint in the United States Circuit Court, claiming the right to the ores beneath the compromise ground by virtue of its ownership of the apex of the vein within the limits of the St. Louis claim wholly outside of the compromise ground, from a point on the east side-line of the St. Louis claim between corners No. 1 and 2, 520 ft. distant from corner No. 1 of the St. Louis claim to a point on the west side-line of the compromise strip distant 108 ft. from the intersection of the west side-line of the compromise ground with the east side-line of the St. Louis claim, running from corners No. 1 and 2, where the hanging wall of the vein began to cross from the St. Louis ground into the compromise ground and for an additional portion of the said vein for a distance of 25 ft. to the point where the foot-wall of the vein passed out of the east side-line of the St. Louis lode claim into the compromise ground. These points of departure of the hanging wall and foot-wall from the St. Louis ground into the compromise ground became known as the 108 and the 133-ft. planes.

The case was not reached for trial until 1899. Shortly before the commencement of the trial the plaintiff amended its complaint, making the total damages claimed \$600,000. The trial was heard before Judge Knowles in the United States Circuit Court in the month of August 1899, and resulted in a verdict for the plaintiff in the sum of \$23,209 for ore extracted north of the 108-ft. plane, or from a vein which had its apex entirely within the St. Louis claim outside of the compromise ground. The district judge held that in order to entitle the plaintiff to recover, it must have within its own surface lines the entire apex of the vein from which the ore was extracted. Both parties sued out writs of error, the St. Louis company upon the ground that it was entitled to the ore within the vein to the extent that it had any of the apex within its surface lines, and the Montana company on the ground that the deed conveyed to it all of the mineral beneath the compromise ground, and that as the verdict embraced damages only for ores extracted from beneath the compromise ground, it was entitled to a

judgment. The Circuit Court of Appeals reversed the case on the St. Louis company's writ of error, holding that the company, as the owner of the senior location, was entitled to recover to the extent that it had any of the apex within the surface of its ground, and affirmed the judgment to the extent of \$23,209, overruling the Montana company's contention that the deed conveyed the ore beneath the compromise ground, where such ore was found in a vein apexing partly or wholly outside of the deeded ground. This action of the Court of Appeals was reversed by the Supreme Court of the United States on writs of error sued out by the Montana company, and that court held that the reversal of the judgment of the Circuit Court as to one portion of the case reversed the entire case, and remanded the case to the Circuit Court for a new trial, without deciding any of the points in controversy.

The case was again tried in the Circuit Court in Helena, before Judge Hunt, district judge, sitting as a circuit judge, in May and June, 1905. Judge Hunt, following the ruling of the Circuit Court of Appeals, held that the plaintiff was entitled to recover for the ores extracted between the 520-ft. and the 133-ft. planes, and a verdict was rendered in the sum of \$195,000. Writs of error were again sued out, and the case was reviewed by the Circuit Court of Appeals. It then went to the Supreme Court of the United States, where, on January 14, 1907, (204 U. S. 204), the Supreme Court rendered its opinion that the deed to the compromise ground conveyed all of the mineral beneath the compromise ground, and, as the decision of that point might end the litigation, none of the other questions were directly passed upon. But in his opinion, Justice Brewer raised, for the first time, the suggestion that the deed to the compromise ground carved out a section from the vein.

The Injunction Dissolved

When the mandate was filed in the Circuit Court, the Montana company moved to dissolve the injunction, which had been granted at the time of filing the original complaint, restraining the Montana company from extracting ores from beneath the compromise ground, basing its motion for dissolution upon the decision of the Supreme Court of the United States that the deed to the compromise ground conveyed to the Montana company all of the ores beneath its surface. On March 30, 1907, Judge Hunt, district judge, sitting as a circuit judge, granted the defendant's motion and dissolved the injunction. The St. Louis company then applied to the Supreme Court of the United States for a modification or an explanation of its opinion relative to the construction of the deed, but the Supreme Court denied the application without any further opinion. The St. Louis company then, on August 28, 1907, made an application for leave to amend its complaint so as to claim damages for ores extracted from the vein on its dip after it had passed through the compromise ground, placing its damages at \$500,000 for ores ex-

tracted from that portion of the vein on or about June 30, 1893, and for \$500,000 for ores extracted from that portion of the vein between June 30, 1893, and the date of tendering this amended complaint. It also alleged that the foot-wall of the vein was at all points either in the compromise strip or the St. Louis claim, and passed out at some indefinite point across the south end-line of the St. Louis claim as patented; the contention of counsel for the St. Louis company being that under the Supreme Court decision, the St. Louis company owned all the ore in the vein after it had departed from the compromise ground on its dip, so long as any part of the apex of the vein lay within either the compromise strip or the St. Louis claim.

This proposed amended complaint not only extended the surface area in which was embraced the apex of the vein from which the ore was alleged to have been extracted, but carried the place of trespass into the depth of the mine and into stopes which had been taken out many years before the filing of this amended complaint, which ore, it was contended by the St. Louis company, was of the same rich value as that taken from the compromise ground near the surface. The proposed amended complaint also set forth the fact that the Montana company had worked out the remaining vein belonging to it, had ceased its operations in Montana, and was in an insolvent condition, having no property within the jurisdiction of the court, except the practically dismantled mining plant. The plaintiff asked for an injunction on the equity side of the court restraining the Montana company from mining upon the compromise ground, notwithstanding the decision of the Supreme Court of the United States that the ore beneath that ground belonged to the Montana company, basing its right to an injunction upon the allegation of insolvency and inability of the Montana company to respond in damages in the event that the St. Louis company recovered judgment, and that the St. Louis company must necessarily recover judgment in some amount, because the portion of the vein from which the ores had been extracted was, by the decision of the Supreme Court, awarded to the St. Louis company.

This construction of the decision of the Supreme Court by the attorneys of the St. Louis company was assailed by the attorneys for the Montana company upon the ground that the declaration of Justice Brewer in the opinion of the Supreme Court that the effect of the compromise deed was to carve out a section of the vein, leaving the remaining portion unconveyed, referred only to the portion of the vein on its dip where

all or a part of its apex lay within the St. Louis claim, and had no reference to the vein after its apex had wholly passed into the compromise strip, and that the Supreme Court by its refusal to modify or amend its mandate had practically so determined. Objection was also made to the filing of this amended complaint upon the ground that by extending the point of departure of the foot-wall from the 133-ft. plane to a point across the south end-line of the St. Louis claim

FIG. 3.

there was brought into the litigation a trespass upon an area of ground not embraced in the original ground, and that as to that portion of the damages claimed, the statute of limitations had barred recovery. These contentions were finally overruled by the Circuit Court, and on December 2, 1907, leave was given to file the third amended complaint, the defendant then answered, and on January 10, 1908, Judge Hunt issued an injunction restraining the Montana company from extracting the ores from beneath the compromise strip pending the litigation. This injunction was unique in the history of mining litigation in Montana, in that it restrained the Montana company from extracting ores from the portion of the ground awarded to it, in order that these ores might be preserved to answer any judgment which might be recovered against the Montana company for trespass upon the portion of the vein which, it was claimed, the Supreme Court had awarded to the St. Louis company. An appeal to review this action of Judge Hunt was taken to the Circuit Court of Appeals for the Ninth Circuit, and on

March 2, 1909, the action of the Circuit Court was affirmed.

The case then came up for trial again before Judge Hunt in 1909, commencing June 14 and ending August 11. Before and during the trial extensive explorations were made upon the surface ground, and the case was bitterly contested by the experts of the two parties as to the position of the foot-wall. At the close of the testimony on behalf of the Montana company, the St. Louis company amended its third amended and supplemental complaint and replication by withdrawing the allegation of the compromise ground as a part of the St. Louis claim, and substituting in lieu thereof the allegation contained in the former complaints that the compromise ground was and always had been a part of the 9-Hour claim. The complaint was further amended by alleging that the apex of the vein in controversy passed entirely into the compromise ground

recovery upon new allegations of fact, upon which they confessedly could not have recovered under the complaint as it stood up to the time when the Montana company was required to present its evidence. Under the pleadings as they stood up to this time, a portion of the apex of all the vein in controversy lay within the compromise strip, and the compromise strip "was and always had been a part of the St. Louis claim," which part had been conveyed to the predecessors of the Montana company by a conveyance prior to that by which the remainder of the St. Louis claim had been conveyed by the same grantors to the St. Louis company. Under the law the effect of the first deed—that conveying the compromise strip—was to convey all of the vein on its dip so long as any part of the apex lay within the compromise strip. By this last amendment, the St. Louis company was permitted to take the position that the compromise strip "was and

always had been a part of the 9-Hour claim," thus presenting a question of rights on the dip of a vein, the apex of which was divided between the junior 9-Hour claim and the prior St. Louis location, thereby presenting entirely different questions both of law and fact. The controversy by this last amendment then narrowed down to the question as to whether the foot-wall passed into the compromise ground at the 133-ft. plane or at a point farther south, designated as the 268-ft. plane. The jury found that the foot-wall entered the compromise ground at the 133-ft. plane (as contended by the witnesses of the Montana company, who maintained that the apex of the vein was only about 10 ft. wide, as against the assertions of the St. Louis witnesses that its width was 55 ft.), and awarded the St. Louis company damages for the amount of ore extracted from the vein after it had departed from the compromise ground, aggregating 1912 tons, valued at \$237,470.40. The court had instructed the jury that if they found in favor of the plaintiff, they should include in their verdict interest at 8% per annum on the value of the ore ex-

tracted in 1893. As nearly sixteen years had then elapsed, the interest amounted to considerably more than the value of the ore. From the above amount was deducted the value of 218 tons of ore taken by the St. Louis company from beneath the compromise strip, amounting to \$34,341.38, including interest, making the verdict \$203,129.02. Upon a writ of error the judgment was reviewed by the Circuit Court of Appeals, where it was affirmed (183 Fed. 51), a petition for a writ of certiorari was denied by the Supreme Court of the United States on March 6, 1911. The Montana Mining

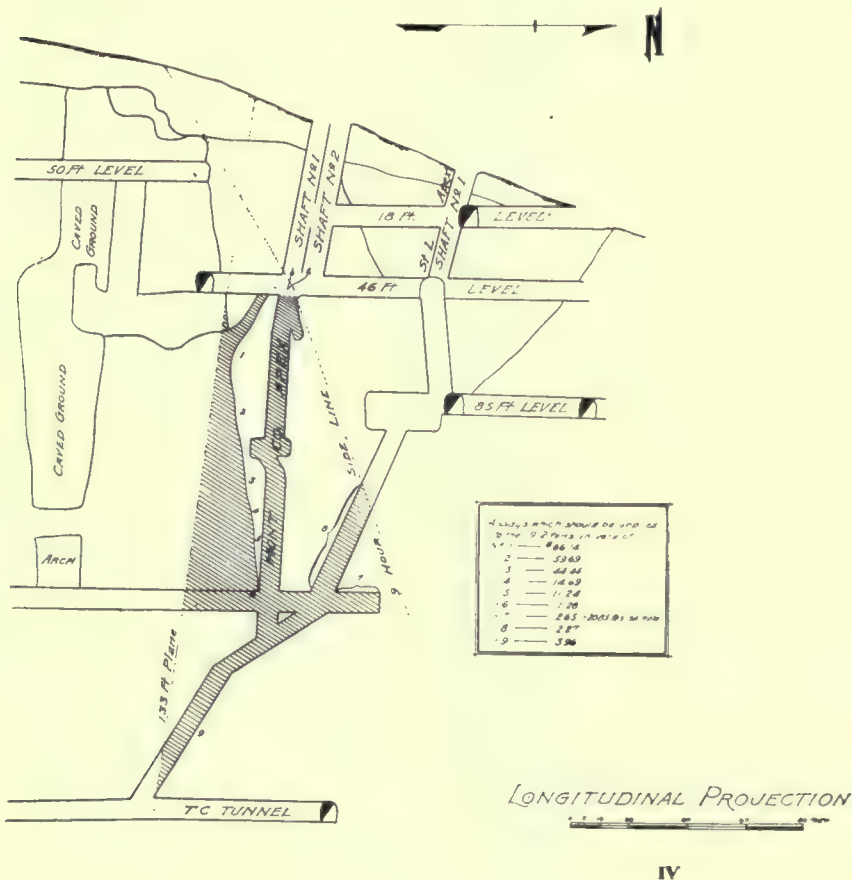

FIG. 4.

at the point designated as the 268.6-ft. plane. This amendment, which was strenuously objected to by counsel for defendant, and was made after the granting of a sweeping injunction upon the construction of the Supreme Court decision, urged by the St. Louis company's counsel, and after defendant had been compelled to prepare its defense of the cause to meet such legal theory, and after all of the evidence in chief of the St. Louis company had been introduced upon this theory—permitted the St. Louis company to completely somersault in its legal position, and seek a

Co. decided to offer no further resistance, and in due course the property was sold by the sheriff to the plaintiff.

In the foregoing chronology of the litigation and analysis of court proceedings, Messrs. E. C. Day, C. F. Kelley, and L. O. Evans have kindly given me great assistance. Reviewing, again, the court proceedings, shows that the litigation in its various phases required in the aggregate about five months in the four trials on questions of fact, and that it reached the State Supreme Court once, the Circuit Court of Appeals five times, and the Supreme Court of the United States four times. Furthermore, much time was occupied by the courts in many preliminary hearings.

Comments on the Verdict

The jury by its verdict showed that they did not accept the wide vein theory of the plaintiff, for if they had they would have awarded him damages for the proceeds of 31,592 tons of ore, instead of for 1912, which was about the amount admitted by the defendant as having been extracted by it under its own surface, but from that part of the vein having its apex partly within the St. Louis claim west of the compromise strip. The award of \$237,470.40 must have placed an original value of about \$55 per ton on the ore. Fig. 4 shows the extent of the excavation made by the Montana company north of the 133-ft. plane and east of the compromise ground, and nearly all of the work was done in and beyond the extreme northern limits of the pay ore. Many samples were taken before the trial from the ore remaining in these workings and the assays were submitted in court, giving what was thought ample proof that the material extracted did not return the company a profit of \$15 per ton. Samples had also been taken as the work progressed, but the samplers and assayers of that time were either dead or out of reach, and the Company could not prove its records by personal testimony. Furthermore, believing fully in the validity of its title to the compromise ground and to all the mineral therein contained, and that no adverse rights could be successfully claimed beyond this strip and within the 9-Hour location, as patented, the defendant had not taken the precaution to run the ore in question through the mills by itself, thereby placing on record its billion yield. Moreover, there was an advantage in working it with ore from other parts of the mine.

The advocates and defenders of our mining law insist that in no way except by giving the discoverer of a vein the right to follow it on its dip under adjoining ground can he realize the full benefits to which he is entitled, but in the case under review, the plaintiff was not suing for any rights directly pertaining to his discovery vein. His demands were based entirely upon an incidental vein, the existence of which was unknown to him when he made the St. Louis location, and this vein only skimmed along his side line, but the actual discoverer of the lode in question, or his succes-

sors in interest, finally lost the entire property as a result of these demands. With no development along the vein, the strike in the 9-Hour discovery led the locator to believe that in compromising with the St. Louis he would have the apex of the lode within his claim from end to end, and from all considerations of equity and justice, the worst that should have happened in consequence of his lack of knowledge of the course of the vein, should have been the loss of the ore included within the vertical boundaries of the St. Louis claim, excluding the compromise ground. But what happened? By the application of the apex law, he was deprived of all ore in the vein he had discovered up to the 133-ft. plane, and was adjudged to be liable in damages to the St. Louis company for more than \$200,000, covering 1912 tons of ore which he extracted from under his own surface. Furthermore, if the jury had accepted the wide vein theory of the St. Louis witnesses, and had given them extralateral ownership to all the ore up to the 268-ft. plane, the 9-Hour locator would have had no rights in his discovery shaft, and would have been a trespasser, and liable in damages, when he took a little sack of ore from there to the assayer, so that he could support the affidavit in his location notice, that he had made a valid discovery.

Can anyone describe an instance where such injustice has resulted in the operation of the mining laws of other countries? With extralateral rights abolished, underground rights would be settled quickly on mathematical planes, and years of litigation, with attending costs, would be avoided.

South Dakota has a forest law which Government Forest Service officials hold up as a model for Western states to copy, claiming that its enactment and enforcement would not only conserve timber, but would, through preventing fire, have an important effect on water supplies. The Service calls attention to the fact that the timbered mountains are the areas upon which the people of the West are absolutely dependent for their water supplies. The law is, in part, as follows: "Any person who shall cut any timber upon any common school or other lands within this state, shall pile up and dispose of all brush and debris in such manner and under such regulations as may be prescribed by the board of school and public lands, and shall commit no waste or unnecessary damage to the standing trees and young growth."

There was no railway construction in Alaska during 1913. Of the 466 miles of track previously built, only 260 miles was operated in 1913. This is largely due to the high cost of fuel and to the tax of \$100 per mile on all operating lines. These conditions have tended to discourage the railways, especially those which are only partly completed. In 1913 the White Pass & Yukon, the Copper River & Northwestern, and the Tanana Valley railroads were the only lines to be continuously operated, according to Alfred H. Brooks, of the U. S. Geological Survey.

What is the Matter With Prospecting?

A REJOINDER

Fayette A. Jones:—It is with much interest that I have noted various opinions relative to the decline in prospecting. Of the various views presented none, from my viewpoint, has even approached the fundamental cause of the prevailing blight. The true reason is not hard to find and the answer is simple: demonetization of silver did it. The incentive for making new discoveries was ruthlessly swept aside by demonetization and the prospector's chances of success declined fifty per cent.

E. W. Reuther:—From reading your vital question, 'What is the Matter with Prospecting?' I am very glad to learn that there is a spirit of concern about. I only wish it may ripen again the fruits of enterprise. There are a few loyal remnants left of the legions that used to work under the customs and rights of the old mining districts, and they are still anxious for a chance to earn their grub stakes or to do assessment work on the claims of others under fair conditions—an eight-hour day, and wages at \$3.50 per shift. Conditions have changed since the old days. Big corporations now take up land which was staked for mineral claims and use it for other purposes; and they have the assessment work on mining claims done by foreign laborers working ten hours a day for a wage of \$2.50, thereby depriving the prospector of the support that he needs to enable him to find new mining districts. Every fair-minded prospector is independent and self-reliant. All he needs is a reasonable reward for his labor and a fair chance. It would be only fair to ask for indirect government support by means of laws providing that all assessment work be performed only by citizens of the United States or persons who have signified their intention of becoming citizens. As our Government is a co-partner in all mining claims, I can see no just reason why alien laborers should be the chief benefactors under the requirement of the annual expenditure of \$100 per claim. There should be an 'assessment inspector' to see that the annual labor on every claim is performed, and a record should be kept of all claims inspected by him. In case the assessment work is not done the owner should be compelled to forfeit his property, or to pay a fine of \$100.

John C. Molder:—The prospector was driven out by recent legislation in the mining states, for every new law has been against him. For instance, Arizona passed a law that a prospector could not re-locate his claim. A few years ago a law was passed in Arizona authorizing the State University to do assaying for prospectors, with a charge of 50c. for a gold-silver assay. The next legislature increased the charge to \$1, because it was said that the lower charge ruined the business of the regular assayers. To encourage

prospecting, each mining state should have a free assay office to which a prospector could send samples of ore that he might wish to have tested or assayed. A prospector never has much money, and if he finds a strange mineral which might be valuable he can seldom afford to have it tested. If a property is being worked for certain metals (such as gold, silver, or copper) and a prospector discovers a deposit of a different kind of metal or mineral, he should be allowed to develop it and acquire ownership. Every county should have a collection of ores and minerals so that the prospector may compare his 'finds' with the known ores exhibited. The taxes from one good mine will pay all of the expenditures made on behalf of the prospector. After a prospector has worked for years and has spent his money trying to keep up the assessment work on a claim, the courts should allow no one to take it away from him. The state or federal government ought to have engineers and geologists to examine all prospects and small mines, and their reports should be on file so that a prospective buyer may be able to secure reliable information. This would help the prospector to find a market for his properties. As a rule the prospector gets very little from his discoveries. Protect the prospector from claim-jumpers and swindlers. Open wide the gates of opportunity and he will find his way through.

H. S. Hite:—The land that is open for prospecting, in this state especially, has been pretty well gone over, but there is still a great deal of ground for the lonely prospector. The land, however, is controlled by companies or corporations that will not allow prospecting because they hold agricultural titles. Then comes the individual agriculturist who does not want any 'coyote holes' dug in his ground. Again, there are some of these agriculturists that are willing to have a prospector go on the ground providing he only wants about one-tenth of what he finds.

I know of much of this so-called agricultural land upon which you can raise a good prospect, and that is about all you can raise, as it will hardly support the wild native vegetation. Some of this land has been held by mineral locations, and afterward the same people that swore it was mineral land swore that it was non-mineral. If there were some way to get at this ground, so that the man with the pick and pan could see what was in it, some of the old-time prospectors would come to life again, and it is more than likely we would have some more good mines and more money spent for prospecting. No prospector cares for a lawsuit, and not many mining men that have capital to spend on prospects care to go to law over land that is claimed as agricultural.

Frank P. Davis:—I believe you could get at this subject better by means of a response from the prospector himself. I have followed that line for 35 years, and I think I ought to say something from my side of the fence. For the past five years, money has been closer and harder to get for developing prospects than ever before. Outside of a few low-grade copper mines, nine out of ten of the new properties that have been opened and put in the mine class in the past ten years have been developed by the prospector and lessee, not by the capitalist. You will find a great number of the old-time prospectors at the present time in some out of the way place or in some idle mining camp, holding down a few mining claims which they are developing as fast as their limited means will allow, while waiting for a buyer. It seems that capital wants a mine for a prospect price. Nowadays if a prospector is lucky enough to go out and get someone with capital to look at his prospects, this is generally his story.

If the prospect looks good to the capitalists they will ask the price of the group of claims, and will be told five or ten thousand dollars, or whatever figure the price may be, with a year's bond and lease, but the owner wants five or six hundred dollars down. Now the showings on this prospect may look good enough to warrant some work and perhaps the expenditure of from ten to fifty thousand dollars in development. But the capitalists will pay nothing down. They do not stop to think that the prospector has done many a hard day's work showing up what is in sight. He probably owes money for his supplies and equipment, but he can get nothing down for what he has put in. There are many good prospects lying idle because of this averseness to paying a few hundred dollars in cash. It seems that many of the mining engineers who are sent out to look at a prospect are not competent to do so. They come with the understanding that they are going to examine a prospect, price probably \$5000. If they don't find a mine, they turn it down. What is the reason? They don't stop to think that if the showings were as good or better two or three hundred feet deeper the property would be worth twenty times as much as the price asked. They work on the theory that only one prospect out of a hundred makes a mine. In earlier days any fair looking prospect, that had the 'ear marks' of a mine, would be taken up quickly, but it now seems that the only thing which will interest capital is a big boom and lots of talk.

The Government can be of great help to the prospector, and be the cause of many discoveries. The prospector in the field has a very hard time to get his samples assayed. Let the Government start good assay offices in the different western states, where a bona fide prospector could get an assay or an analytical test on his samples without paying cash. Then the \$100 annual assessment work on a mining claim ought to be done away with. Have an annual tax, say \$10, for each claim. This would be much better in more ways than one for all concerned, except the few who make

a living by doing assessment work (and a kick from the miner's union). A part of the tax could be used for the maintenance of the assay offices. Prospecting, in one sense, is much easier today than it was years ago, as the thousands of feet of development done in late years are really a great help, whether ore has been discovered or not.

W. S. G. Todd:—On behalf of the prospector, I wish to say that too much credit cannot be given the man who has the nerve and inclination to throw a fry pan, coffee pot, a little plain grub, and a roll of blankets upon a 'jack' and hike for the unexplored mineral regions. He must find mineral that will pay, or his grub and time, which are his stock in trade, are lost. He stakes everything he has. If it was not the prospector who made the first move toward bringing into existence the mines that in 1913 produced about \$88,000,000 in gold in the United States, I should like to know who did. Suppose a prospector makes a promising find. He has no capital, but as long as his grub lasts he is hard at work, and he opens up his ore on the surface as best he can. Then what happens? He is compelled to go to work for wages or look for some one with money to help develop or buy his prospect. The prospector struggles along doing such development as is within his means, hoping someone will come along who is willing to take a chance with him. Finally someone does come. He looks over the property, and perhaps the district, and concludes that both look promising. He takes a round of samples, the best high-grade he can find, and starts down the trail. He doesn't go far, however, until he relieves himself of the test samples, but not of the high-grade. That is his pay-streak, for he may be out several months, during which time he takes up quite a collection. He does not return. He is an imposter, but he creates a bad impression with the prospector.

The prospector's next experience is with the 'shoe-string' promoter. Men of this class are pretty well represented. They float around through the mining country taking options and bonds on everything that looks at all promising. They want to secure options for from three months to a year or more. They are close to millions and will take your proposition up at once, but of course 'you know we can't hurry the big fellows.' Now, as a matter of fact, about as near as these fellows ever get to money is in passing a bank. Should one of them happen to reach real money, he usually doubles the price of the property, with the result that the whole matter will be dropped immediately after an examination. The poor mine gets the blame, and the capitalist becomes more cautious. This method causes the report to be circulated that a prospect or small mine cannot be bought at a fair valuation. We are surrounded today by conditions caused largely by too much middleman, and mining has come in for its share of the bad resulting from it.

Finally, the prospector may take a trip to the city and may call upon Mr. Goodfellow. After giving a de-

scription of his property, the prospector is informed that Mr. Goodfellow has no clients at present who would care to develop a prospect, but he has a friend who is in touch with capital. The prospector then describes his property to this man, who informs him that he controls considerable money available for mining, but at present he has none for developing prospects, the demand being for developed properties. However, he knows of some local people who might be interested. Before leaving, the prospector is given to understand that in case any business is done, both he and Mr. Goodfellow will have to be taken care of to the extent of about 10% each. In the course of time the prospector is brought face to face with the man who really has capital. He listens attentively, says that he is somewhat interested, but does not think it is just what he wants. In fact, if you had just what he did want you could work out your own salvation with a hand mortar. So finally, with shoes and patience worn out, the prospector returns to camp.

I am strongly in favor of government aid to the prospector, for the simple reason that he cannot get it from any other source and get a square deal; and I believe he is entitled to at least a small portion of the benefit to be derived from the property he has discovered. I note the opinion has been expressed that under no condition is aid to the prospector a function of the Government. Now, in my opinion, it not only is a function but a duty of the Government to aid in every way possible the development of the resources of this country, and the people who are engaged in it.

H. Pembroke:—I am much surprised at the statement of 11 out of 18 writers that there is plenty of money for the development of prospects. This is the reverse of the experience of the prospector, most assuredly, and it is mainly for this reason that prospecting seems to be on the wane. If there is plenty of capital, I should like to ask Mr. Thayer what is the proper channel through which the prospector can reach it. The past few years have seen the growth of huge corporations that have indirectly controlled prospecting, mining, and smelting operations. It is stated that one corporation selected one or two properties out of over 700 that were presented for its consideration. It is not stated why this wholesale rejection, but it would not be safe to say that the 698 lacked merit. Is it not just possible that a great deal of the trouble is right here—control of the capital, production, and the market through certain metal-selling agencies? If that is the case, as a banker, Mr. Hayden is quite right in saying, "I do not believe there should be any better market for undeveloped lands created."

Who is the wise man of the East or West who is to tell the value of an undeveloped mining property? My memory goes back to a certain miner who drove 1900 ft. in a certain mine before 'striking it.' He then went to a certain banker, offering part of his stock at \$4 per share. It was declined until a certain Hebrew bought some of it. Then the banker (who

was not a Hebrew, by the way) took hold of it. This stock was about \$7 for a year or so, when it began to climb until it reached \$55 per share. The property has produced millions; it still produces. There is a certain mine in Eureka, Utah, upon which \$180,000 was spent before a pound of ore was found. Then this same banker was offered a large number of its shares at 40 cents. He sent an engineer to examine the property. He advised rejection. This stock rose to \$2 almost immediately, and this mine has also produced millions. There are a number of such instances in every field. The point is: who is competent to say whether a prospect will make a mine or not? And who is thus qualified to speak of the rejections; who rejected them and why? Again, where is the wise man!

Referring to the engineers' statement that there is plenty of capital for prospectors—where is it? Can they get it? Can they tell the prospector or miner how to get it? They cannot. I mean, as a class they cannot, because the average engineer is a very cold blooded animal. He realizes his limitations—he cannot see farther than the point of his prospecting pick, any more than the prospector can. (I say nothing about his technical ability to prognosticate upon the signs that are about him.) And the average engineer will not make a positive statement that the capital will come back to its investor. He cannot. I have had unusual opportunities to study the engineer, and my sympathies are surely with him. If there is an abused profession it is his: abused because of things absolutely beyond his control. Full and complete discussion of this question will do good. I compliment you on your effort. Keep the good work going. Let us learn just where the trouble is. We must all remember that "the mining industry is the avenue through which flows the imperishable wealth of the world; that from no other source can gold and silver and the baser metals be secured."

S. A. Knapp:—I have read with considerable interest the remarks of the several gentlemen published in your symposium relative to prospects, prospectors, and prospecting. Having had a considerable experience with the subjects mentioned in California, (and in Nevada from 1876 to 1905), during which period I have staked a large number of prospectors, and been interested in numerous prospects, I would say as the result of my observations: (1) That it takes prospects to make mines, as all mines must necessarily go through the prospecting stage. (2) That it takes prospectors to hunt up and find the prospects as a rule, although accidental discoveries have been numerous. (3) That prospecting, particularly in the desert regions, means hard persistent work, deprivation, close and careful examination of small details, a good general knowledge of mining work and of the characteristics of various ores, and in any region the successful prospector must be a close observer. (4) That government aid is unnecessary, and would be, I think, unwise: all that the

prospector asks of the Government is covered by Section 2319 of the Mining Law of 1876, to-wit:

"Section 2319. All valuable mineral deposits in lands belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase, by citizens of the United States and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners in the several mining districts, so far as the same are applicable and not inconsistent with the laws of the United States," and the free use of water and fuel on the Government domain, and to be unhampered in his work, or in obtaining title to his property, by red tape and unjust rules.

The true prospector, living in the mining regions, generally has some arrangement with local people, ranging from the merchant to saloon man, barber, farmer, and others, by which he is enabled to obtain supplies for his trips, and with whom he shares his finds whatever they may be—good or bad. Usually many prospects are tried out in a small way before a good one is found, and it takes sand and nerve to keep at it until a good one is found. Very many fortunes can be traced to the successful result of small investments made in this way. It is probable that most of the lodes and deposits in California and Nevada, distinguished by bold and prominent outcrops, have been examined to a greater or less extent. The mineral sections of California have been much more closely prospected than those of Nevada; there are, however, thousands of square miles in the state of Nevada, in which the mineral resources are practically unknown; the country has been simply run over. The improvements in metallurgy and the building of railroads make available ores that a few years ago were practically valueless, and passed by as worthless by the prospectors of that time; zinc and copper ores in Nevada, even on the line of railroads were unmarketable until within the past few years.

In the 80's, the only market we had for copper ores was a limited demand at Dayton, for oxidized ores for the manufacture of bluestone for reduction of Comstock ores. John Ludwig ran a small water-jacket, at the old Ludwig mine, and made some copper. The Blue Light mine smelted about 16,000 tons of 17% carbonate ore at Sodaville, and wore the copper out, shipping it around until they sold it, for the reason that it had considerable arsenic in it. In the desert regions, the scarcity of water and difficulty of obtaining supplies has retarded the prospecting and subsequent development of large areas. When a supply point is established, prospectors work out from that point into the surrounding country, and discoveries are made; prospectors, ranging out from Tonopah, discovered Goldfield, Manhattan, Round Mountain, Clifford, Silver Bow, Cactus Peak, and other promising mineral districts. From Columbus and Candelaria, in former years, prospectors ranged out, discovering the deposits

of Lida valley, Palmetto, Tule cañon, Log Springs, Old Gold mountain, Lone mountain, Monte Cristo district, Marietta, and Klondyke, not quite reaching Tonopah and Goldfield. From Hawthorne, the prospectors worked out, discovering the Hawthorne district, Santa Fé district (now Luning), Mt. Cory district, Confidence district, Garfield district, Kinkead district, Silver Star district, Huntton valley, Whiskey Flat, Lucky Boy, Cat creek, and many others.

Many discoveries have been accidental, and many important properties have been passed by unnoticed. Tonopah was discovered by Jim Butler by accident. The ravine, where the main street is, was used regularly by sheep and cattle men in driving their stock back and forth; they passed within a few feet of large and rich outcrops. The spring supplying water at Goldfield was for years claimed by John Chiatovich, of Silver Peak, and used as a supply for his horse ranch, which covered the present site of Goldfield. In the early 60's an exploration party (of which the late J. H. Kinkead was a member) went down through that section, and camped at this spring for a week, ranging out from there, but found nothing to suit them, and went on; they were looking for prominent quartz outcrops, and the silicious porphyry outcrops of that district didn't look good to them.

In the Silver Peak district, the first discovery was of the Vanderbilt group (silver-lead), in the southern part of the district, made by teamsters hauling salt from the Silver Peak salt marsh to the silver mills at Reese river (Austin). Their cattle were turned out to graze, and strayed up to the hill where these large lodes of good lead-silver ore outcropped, and attracted the attention of the teamsters. Later Reinzi Hughes, a tinsmith from Columbia, Tuolumne county, went to Esmeralda district (now Aurora). Not finding anything to suit him there, and hearing of the find of the teamsters, he went down there. He went prospecting in a cañon about four miles north and discovered the large gold veins upon which the property of the Pittsburg-Silver Peak is situated, and which are keeping 100 stamps dropping regularly. The Garfield district, which produced about \$3,000,000, was found by a wood chopper. The Indian Queen mine, near Benton, Mono county, a large producer, was found by an Indian, who showed it to William Witherell. The first discovery in Bull Frog district was made by an Indian, who showed it to Bob Montgomery. The Rawhide district is on the old Wadsworth road to Columbus (the main freight road to southern Nevada for many years). The lodes were in plain sight, but no attention was paid to them, until a prospector who had learned that it wasn't always necessary to find a quartz outcrop to get ore came along. The new camp of Rochester is in an old mining district, but these large lodes were overlooked and neglected for many years.

Many deposits have been found, worked for a time, and abandoned for one reason or the other, and many of these, when properly developed, will be revived. Among the number are such districts as Grantsville,

Downieville, Ione, Lodi, Benton, Troy, Tybo, Liberty, Aurora (now being developed), Belmont (again to be worked), Candelaria, Silver Star, Garfield, Hawthorne, and hundreds of others. As these are revived and re-established, the prospectors will get to work again; and with better conditions and a better knowledge of ores many more discoveries of importance will be made. The prospector relies, as a rule, on the general average working out. He realizes that he must expect to examine many lodes before finding a good one, and therefore takes disappointments philosophically. Our most successful mining men—Hearst, Lane, Hayward, Haggin; and before them, John Gashwiler, Henry Allen, Isaac Bateman, Steve Roberts, and others—operated on the same general plan, except in a larger way: a promising prospect always appealed to them, and when they reached the position where they could

afford the loss of a few thousand dollars many prospects were examined or developed. If they got one mine out of a dozen trials, and some of these expensive, they came out on the right side of the ledger. Companies organized to operate on this basis, with sufficient capital to handle the properties acquired, are practically certain of success when carefully and economically managed.

Give the prospector a fair show. Help him when you can, if you find him square, if it is only with an encouraging word. When he finds a good prospect, don't try to beat him out of it, but give him a fair chance so that if it proves good he will derive some benefit from his labor and exertions, and he will continue to look for and find new and now unknown mineral properties that will keep up and add to the mineral production, and he won't ask or need any government aid.

A Water-Actuated Sampler

By E. LE ROY

The accompanying rough sketch shows the essential features of a water-actuated automatic sampler, which can be easily constructed and installed in any mill. This sampler is superior to most samplers of the tilting-

WATER-ACTUATED AUTOMATIC SAMPLER.

box type because it is quick in its action and will not stop in the oscillation and flood the sample, owing to accumulated tailing or pulp adhering to the sides of scoop.

The sampler can be suspended by the supports *H* (see sketch) and balanced on the rod *D* which runs through the tilting-box *C* below the false bottom *FB*. The sampler is actuated by a small flow of water, regulated by the petcock *F*, which is connected by a small pipe to the mill supply pipe or if preferred to a low-pressure main. When the water in the tilting-box

reaches the level, it overcomes the gravity of the down side of the box plus the gravity of the swinging ball or weight *A*, and the box tilts until arrested by the buffer *B*. At the same time the scoop *S* cuts the flow of material in the launder *T*, depositing it in the sample pail *Y*, or conveying it to any desired place. As soon as the box tilts, the siphon *G* quickly empties the lower end of its load; and as soon as the weight of water is sufficient, the operation is resumed in the other direction, again causing the sampling scoop *S* to cut the flow in *T*.

The pendulum is the only new feature, and, in my opinion, the important one. Without its use the sampler will start off very slowly and gradually increase in velocity until at the end of the oscillation it is traveling at a fair rate of speed. With the ball or weight always off centre and lending its weight each time to that of the load in the box *C*, it acts, as it were, as a governor and prevents the irregular motion usually seen in samplers without the weights. At the same time it effectually eliminates the possibility of the scoop coming to rest in the stream to be sampled, an occurrence which frequently happens with a sampler of the tilting-box type not provided with the swinging weight. A discarded Aldrich pump valve-ball makes a very good weight, but a piece of lead, a section of rail, or any scrap will answer. Of course, the weight will have to be adjusted as well as the length of supporting wire, to correspond with the weight of the sampler.

Eighty-four machine-drills were worked in the Champion Reef gold mine, India, during the past fiscal year. The cost of compressed air per drill, including system losses but exclusive of air used for blowing out after blasting and for ventilation, was \$533, and maintenance and renewals \$79 per year.

Iron ore output of over 10 districts of Spain was 10,100,000 tons in 1913.

TENSION AND SUPPORTING TOWERS ON LONG SPAN CROSSING VALLEY.

An Aerial Tramway to Chinese Coal Mines

By C. A. TUPPER

With the practical completion of the Panama canal, and partly because of the changed conditions which this will bring about, the attention of mining men and of large industrial interests has been directed forcibly, of late, to the possibilities offered by the coalfields of China. That these are of tremendous extent has been known to geologists for many years past. From superficial but fairly comprehensive examination of outcroppings in provinces near the coast, some English and German authorities have arrived at the conclusion that the known deposits, both of anthracite and bituminous, exceed in value those of all other countries combined. While this may be, and probably is, an exaggeration, the fact remains that the beds cover, in the aggregate, a vast area. That the time is fast approaching when Chinese steam coal will become of immense economic importance to the shipping and manufacturing industries of the world at large is also apparent.

Until recently, this coal in limited quantities was recovered entirely in open-pit workings or from short, untimbered adits which were driven not to exceed 400 ft. into the hillsides. Such operations were, and in places still are, carried on without the use of machinery and entirely by coolie labor with crude implements and baskets. A good 'mine' produced about

36 tons per day and employed up to 60 men. Within the past few years, however, a number of modernly equipped properties have been opened up by German, English, and Chinese companies, as well as for the account of the Government, and facilities for an annual production somewhat in excess of 3,000,000 tons are now being utilized nearly to capacity. Prominent among the concerns operating are the Schantung Bergbau Gesellschaft, the Chinese Engineering & Mining Co., and the Hanyang syndicate or Hanyeh-Ping Iron & Coal Co., as representatives of the three nationalities principally concerned in developing the coalfields of the country.

It has remained, however, for an association of Chinese merchants, identified with the so-called 'salt monopoly' of Petchili, to undertake the most noteworthy and spectacular enterprise of this kind, that is, the building of a 15 mile aerial tramway, supported on steel towers, to provide for transporting coal from the native mines in the mountains west of Toli to the railroad station at that place for trans-shipment to Peking. The headquarters of this association, which for convenience will be called the Toli Syndicate, are at Tientsin.

While the members of the syndicate do not own or

FROM THE FOOTHILLS TO TOLI.

operate any mines, they have controlled from the first the marketing of a good grade of anthracite brought from the district mentioned, which was packed in on camels and donkeys for the entire distance. With the building of the first railroad south from Pekin, however, a number of small mines were opened along the route, and the competition of this fuel shut off the supply from the Toli workings. Then came the construction of a branch line connecting Toli to the trunk road from Pekin to Wuchang; and the project of bringing in coal from that district was revived. Packing the coal to Toli on the backs of animals would still make the price at Pekin prohibitive, as compared with competing fuel; so the first idea was to extend the railroad line on into the mountains.

Preliminary estimates showed, however, that the expense would far exceed any returns to be expected from traffic, and the topography of the country made construction exceedingly difficult; hence it was suggested by the engineers called into consultation that an aerial tramway be built. This, after due consideration, was determined upon by the syndicate; and the entire planning and construction of the line was entrusted to Adolph Bleichert & Co., of Leipsic, Germany, a firm which specializes in this kind of work.

The tramway, as now completed and put in operation, was built in the form of an elongated Y, so as to tap the three principal centres of production. Starting from Toli, it traverses cultivated fields and terraces until the foothills are entered, about six miles out. There the first outcroppings of coal are crossed and a junction known as Tien-shan has been built. At this point the line divides, one branch finding its terminus five miles up in the mountains at Chin-Chiankon and the other four miles on the opposite side of the district at Hung-Meehan. The fields are, however, nearly contiguous; so that loading stations are placed at intervals between Tien-shan and the two outward termini. From the various mines, which number upward of 600, the coal is brought by pack animals or on coolies' backs to these stations, there weighed and recorded and then dumped into bins. These bins have hopper bottoms, from which the coal is drawn off directly to the buckets of the tramway, shunted in on an overhanging rail track for the purpose. When a bucket is loaded, the carriage from which it is suspended is simply shoved out onto the track cable, automatically couples to the traction cable, and is whirled away in the direction of Toli. At Toli the station contains large masonry bins for the coal, and cars are switched in underneath a loading spout. The line is designed to carry 50 tons per hour, or 1000 to 1200 tons for day and night operation.

For the entire traffic of the system 440 carriers, each unit consisting of a carriage and bucket, are at present in service. The loading stations being mainly at considerable elevations, the operation is largely by gravity; while the steep grades and long spans made it possible to obtain the capacity mentioned with a bucket speed of 8.2 ft. per second, except on the upper stretch of the Hung-Meehan line, where it was made approximately 5 ft. per second. The power generated by the loaded buckets coming down is ordinarily sufficient to carry the empties up; but any energy needed to prevent a stoppage of traffic, and also for breaking where necessary, is provided by six power-plants. There is one of 80 hp. at the Toli station for the first six-mile stretch, also 15, 13, and 6-hp. plants on the line to Chin-Chiankon and 25 and 15-hp. plants for the Hung-Meehan route. Each of these consists of a locomobile, the top of the boiler forming the baseplate of the engine, a very compact, easily transported unit for isolated service.

Thorough and easy control is maintained over the traffic. A tele-

phone line is strung along beneath the cables, and before the tramway is put in operation each morning, which takes place from above, all stations report to the dispatcher that the track is clear. As soon as this is understood, the traction cable is started up at reduced speed and a load sent from each of the upper termini. Then the loaded buckets follow one another from the different stations, with gradually increasing frequency and acceleration, until the line is loaded to its capacity and the velocity of travel has become normal.

With the tramway fully loaded, the operation proceeds almost automatically, except for the distribution of the traffic from the various stations, which is a matter of practice on the part of the attendants in starting the buckets between other down-coming loads. No care has to be given the buckets passing through loading stations, except at Tianshan, nor is any operator required at angle or tension stations. For all of these, where the carriages enter and depart, there are rail cross-overs, with terminal shoes or saddles so designed that the transit to and from the track cables is without any bumping or jarring. These shoes are also provided with hinged steel hoods, which save the cable joints from undue wear.

When the loads arrive at Toli the coal is automatically weighed, recorded, and dumped to the railroad bins. The 'empties' then pass around a loop, unless switched off by the attendant, automatically couple to the up-traction cable, and start on the return journey, to be taken off at stations along the route as needed. There are also special receptacles which can be sent up with supplies.

The carriage used with each bucket consists of two steel side plates, between which are mounted two wheels fitted with phosphor bronze pins and so designed that, as the upper surfaces become worn, they can be turned around underside up. The hanger pins are made of machinery steel. By an ingenious lever arrangement the weight of the load acts as the gripping force, which varies with the inclination of the cable. This construction possesses the advantage of being independent of any nice adjustment of the jaws, so that the grip automatically accommodates itself to irregularities in the wear of the traction rope. The mechanism operating the jaws is entirely enclosed within the main casting, and it is impervious to the elements, which makes it possible to operate the tramway under the severe weather conditions sometimes obtaining in the mountains west of Toli, including the occurrence of heavy sandstorms.

The types of supporting towers can be seen from the illustrations. These are of structural steel, light or heavy as the conditions along each stretch require, but of ample strength in every case to sustain the heaviest possible loading of the line and with large factors of safety. They were riveted together on the ground, then raised and secured to masonry or concrete foundations. The spacing of the towers was, of course, governed by the capacity of the line and the gradient at the various points. Where long spans were necessary, the usual precautions were taken.

The carrying or 'track' cables were carefully selected for strength and wear, being, for the heavier gradients, of the 'lock-coil' type. The traction cable is of equally good quality for the service required. In a line of this strength it was, naturally, necessary to apply tension to the track cables at suitable intervals, and special tension towers were erected for this purpose in addition to similar arrangements at the stations. The tension weights, suspended in slides, consist of steel cages filled with cut stone; and by adding or taking out these slabs the tension of the line can be varied to suit operating requirements.

The lubrication of the track cables is automatically effected by a traveling oiler. The special compound used is carried in a cylindrical

TYPES OF TOWERS.

tank, to which is attached a small rotary pump driven from the carriage wheels by a belt and gears, forcing the lubricant up through a small pipe to the cable at a point just under the middle of the carriage, so as to exert a spraying effect. There is also a special device for slushing the traction cable. This consists of a U-shaped receptacle containing the mixture used, which is suspended near one of the terminal guide sheaves. The rope passes over a small roller, which slushes it in the same manner as a ring oiler of a bearing, and brushes set just beyond in the receptacle wipe off the drip.

The construction of the line was carried out under

The engineer in charge was, however, a diplomat. Aided by letters from members of the syndicate, he established friendly relations with both the Manchu and Chinese nobles, placated the local magistrates, and through the influence of these classes succeeded in convincing the elders of the villages that no violence would be done to their customs or religion. On the other hand, he pointed out the benefits that would accrue to the district from the money paid for the coal, for labor and supplies, and he spent money liberally in demonstration of his claims. The priests and monks he won over to such an extent that the latter boarded the Europeans throughout the course of the

INTERIOR OF LOADING STATION.

much difficulty. Besides the obstacles interposed by the topography of the country, with lack of roads and bridges and the absence of any facilities for transporting materials beyond Toli, a plague broke out among the laborers and the erectors encountered violent opposition from the inhabitants of the districts traversed.

The chief objection of the natives arose from the threatened desecration of their ancestors' graves and also from the fact that men working on the tramway would be able to look down into the inclosed gardens where the women and girls were secluded. Furthermore, the priests and monks along the route discovered that the tramway would pass over or along their temples and monasteries, so that their opposition was added to the hue and cry against the 'foreign devils.'

work, giving them lodging in the hillside monasteries.

Besides the supervising engineer, there were six erecting men sent out from Leipsic. Work not done by them was performed by Chinese artisans recruited on the ground.

Progress was greatly aided by the fact that every piece of steel or other material sent out from Germany was in just the right shape to be put together. As each section of the tramway was completed between stations or any point where a terminal could be temporarily rigged up, it was utilized for transporting men and materials, much as a railway is pushed forward, and this also helped to solve many difficulties. The line is now in successful operation; and one of the results of its construction will be the development of the Toli coalfields along modern lines.

From the Capitalist's Viewpoint

By ADOLPH LEWISOHN

"In an address which I recently made to the graduates of the Columbia School of Mines, I gave my views regarding the mining industry of this country. I said that I considered mining enterprises, with the assistance and advice of the right mining engineers and experts, safer from a business standpoint than farming and industrial enterprises, and, therefore, I think it most important to give the young men the very best opportunity for a thorough education in the science of mining and metallurgy. The ore from which the results are obtained is already in the ground, and it is only a question of the time and the method of extracting same and producing the metal therefrom. Crops, on the other hand, have to be grown, and depend greatly upon the elements and many other conditions which are beyond our control.

In the business of mining, success depends largely upon the ability of the engineer or expert to determine correctly the grade and approximate quantity of ore that is in a given space in the mine, and the metallurgical treatment which will give the most satisfactory results. A farmer may have all the necessary knowledge and ability and yet may not be able to obtain good results under certain adverse conditions as above mentioned. The success of industrial enterprises depends greatly on the ability to procure the raw material from those who produce it and to manufacture it into the finished article at a price which will leave a profit. The raw material in a mine is supplied by nature. It does not have to grow as crops do, but is there ready to be taken out at any time, and the results depend greatly on the reliability

of the mining engineer or expert and his ability to correctly determine the quantity that can be extracted and at what cost. The market price of the metal may vary, but well trained, experienced men can form a fair judgment as to this. As a general rule, a mining enterprise that is able to produce the metal at not higher than the average cost of production should be able to compete with the other producers and be considered as good enough to enter the field of competition.

The capitalist must be able to form a judgment as to whether he can furnish the necessary capital, either himself or jointly with others, who will make the investment under his leadership. He, with the advice of the engineer or expert, must determine whether the enterprise is good enough and will likely turn out to be successful and profitable, and whether he is able and willing to furnish the necessary capital to bring the enterprise into successful operation. Much, therefore, depends upon the action of both the capitalist and the engineer. No business is more dependent upon accuracy than the mining business, and, while the mining expert must have some imagination, he must be able to tell exactly what is based upon actual knowledge and what represents merely imagination. He must tell plainly what he actually sees, and must have the knowledge to enable him to advise how to treat the ore and to figure the cost of treatment, so that the capitalist can judge whether it can be made a commercial success. Honesty and frankness are also absolutely essential. If the mining expert does not know, it is better for him to say so. With accurate information before him, the capitalist can do his part and by experience will be able to judge whether the enterprise can be carried out successfully. Under these conditions I consider that mining is a good and safe business.

Precipitating gold from cyanide solutions on zinc wafers was found to be a success by John S. MacArthur at Caveira, Portugal, but not on the Rand or at Waihi. Mr. MacArthur now thinks that precipitation is aided by the presence of mercury and lead in solution, the

former metal sometimes equaling the amount of silver in quantity, and the lead is generally only a fraction of the silver present. The precipitate tested by him contained 35% of mercury, which is recovered by distillation.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

California Miners and the Exposition

[The article published in the *Mining and Scientific Press*, January 31, has caused so much interest that we take pleasure in printing a few of the numerous letters received by Mr. van Barneveld regarding the proposed state mining exhibit.—EDITOR.]

Sir—I have read the article in the *Mining and Scientific Press*, outlining the plan for the mining industry of California, with much interest. It seems to me that if this plan can be adequately carried out it will insure a most interesting and instructive exhibit which would be of material advantage to the state and to the mining industry. I will be very glad to do what I can to make this plan a success, and will be glad to have you advise me further as to the practical means that may be decided on to put this plan in operation.

G. W. METCALFE.

Sir—Your conception of the purpose and object of the exposition meets with my full approval, and I also agree with your idea that the mining industry, and particularly the industry of this state, should make an exhibit which will command widespread attention. There can be no doubt that a comprehensive, well arranged, and coördinated state exhibit will represent the importance of mining in California far better than a series of detached and unrelated county exhibits. I see no other way of properly emphasizing the importance and size of the oil and mineral resources of California, except by means of such a state exhibit. The construction, as you suggest, of a model mountain illustrating methods of mining and methods of oil production will make a very interesting and imposing centre exhibit in the mining building, and I think it is proper that the name of California should be associated with such an exhibit, because of California's position as a gold and oil-producing state.

S. W. MUDD.

Sir—Everywhere we hear that money is scarce, but as every little thing helps by joining the efforts and good will of all the miners and mining men and mining engineers interested in placer mining, I believe the proposed plan will answer the purpose and fix a date in the placer mining industry. This plan does not prevent each individual, each county, having an individual exhibit if desired, but individual exhibit or county exhibit will not impress the public, which when visiting the exposition has no time for details and needs the *ensemble*. In the mining industry California has a unique situation, and there is no other place on

earth where so many and varied mining methods can be applied, and the grouping of them in few separate units which can be seen at once is certainly going to bring success.

PIERRE BOUERY.

Sir—I read with much interest your article, 'California Miners and the Exposition,' in the *Mining and Scientific Press* of January 31. I fully agree with you, "the proper place for California's mining and oil exhibit is unquestionably the Palace of Mines and Metallurgy," not in separate county exhibits where there probably would be many duplications. Moreover, by reason of lack of funds, or limited variety in mineral product or both, it would be impracticable for counties to make a comprehensive well worked out and interesting mineral exhibit. I commend your plan, and shall be pleased to assist you in any reasonable manner.

HAROLD T. POWER.

Sir—Your idea of centralizing the mining exhibit, as outlined in the *Mining and Scientific Press*, January 31, appeals to me as being a very excellent one. It is unfortunate that no funds have been provided for a state exhibit, but it would seem, therefore, that the individual counties would be more justified in assisting in the financing of such an exhibit out of exposition funds which they are raising by taxation. I believe, if the matter were sufficiently strongly brought to the attention of the counties, that something could be done in the direction indicated.

JOHN B. KEATING.

A Blacksmith's Problem

The Editor:

Sir—The blacksmith here at the mine is having considerable trouble in making his steel stand the rock, which is a diorite containing much feldspar and rather hard quartz. He is also having trouble with his picks. Could you tell me what temper he should give them, and what he should put in the water?

W. S. DOOLEY.

Adin, California, January 24.

[Doubting whether any general rule could be laid down to cover such a case, we referred this inquiry to T. H. Proske, whose long experience enables him to speak with authority. Mr. Proske has sent us the following.—EDITOR.]

The Editor:

Sir—Your letter of January 30 came to hand several days ago, but I was so busy that I did not have time to answer it promptly, and trust that you will pardon my neglect in this matter. Referring to the letter of Mr. Dooley's, I will say that his situation reminds me of the story of a young lady who was telling a friend of hers how to make a young man propose. Her advice was "to brighten up the parlor, have a nice fire in the grate, dress herself up real neat and tidy, have the light turned low, and when the young

man arrives escort him to the sofa, sit down beside him, and if he didn't 'pop' pretty soon, it was time to change the man on the sofa." My opinion is that it is time for Mr. Dooley to change the man on the sofa. If he is a man that knows his business, he will demand good clean coal, good clean soft water, and a good grade of steel; then he will solve the problem of making his steel stand up to the work it has to do. If he is not capable of doing this he is a costly luxury to Mr. Dooley.

I remember an experience I had at one time at the Granite mine at Cripple Creek. I had several brands of steel, and it took some time to get them separated and to learn the proper heat for tempering each. During this time I experienced some trouble in getting the various kinds of steel to stand up, but once I had it all separated and marked, I had no trouble. One day a new lot of steel without any brand on it came in. The shipper advised that it was a certain brand and grade. As the steel was made up but not tempered, it was up to me to temper it for the first time. Acting on the advice I had as to the brand and grade, I proceeded to temper the steel, and every piece came back to the shop broken. The superintendent was furious, but I told him to keep his temper, that I had been lied to about the brand and grade, and assured him that I would make this steel stand up if it were possible. If not, I advised that it would be best to return it. Exercising some care the second time and tempering at a lower heat, I made a success at once. None of the steels broke and only one or two were soft.

No fixed system can be worked out to temper the various brands and grades of steel. What is best for one grade or brand will not do at all for another; a heat of a certain degree will harden the bit just right for one steel, make it too hard for another, and not hard enough for another. It is safest to stick to one grade and brand, then put it up to the blacksmith to temper it right. It is not best to change steel every time the blacksmith is changed, but insist on the blacksmith changing himself to the steel. If he is not flexible enough for this he is not a good man.

T. H. PROSKE.

Denver, Colorado, February 10.

Ore

The Editor:

Sir—The differentiation between the terms 'ore' and 'waste,' in the mining sense, deals with so many variable factors that it is a very nice balance applying to each mine under its particular conditions, but admitting of little or no generalization; in fact, it is thoroughly recognized in the old established districts that the waste of today is the ore of tomorrow. The definition that could be made so elastic as to cover a rock or mineral aggregate that was ore under one set of conditions and waste under another, would be too cumbersome to be useful. Then, too, it is extremely improbable that the miner can be educated to any

such refinement of language as is contemplated by some of the individuals who are contributing to this discussion.

Extending the matter of correct diction and terminology to radium-bearing rock, it becomes still further complicated, and it suggests another phase of the same question. This in relation to the random use of the words 'radium' and 'radium ores' to designate rock which carries the newly discovered rare element in quantity which is infinitesimal. When one stops to consider that a gold ore comes correctly under the term even though it may have an assay value not to exceed \$2 per ton; and further, that this quantity would represent approximately one-tenth of one ounce per ton of rock, or one-two hundred and ninety thousandth part by weight in the proportion of gold to rock and its mineral components, the use of the word 'gold' begins to be out of all proportion to the quantity factor. The same applies to silver. But when this is applied to the radium content in ore which is radium-bearing, the proportion in Ra/Ur equals, for the carnotite ore, 2.34×10^{-7} , and for the pitchblende ore 3.21×10^{-7} . With uranium itself occurring in very small proportion, the lower grades of both ores is by weight between a three and four hundred millionth part of the weight of the rock mass.

It is unfortunate that the word radium has been so freely used in the designation of low-grade uranium ores slightly radio-active, and unless some reform is brought about, the words radium ore will cease to have any meaning and will become the sport of the dishonest promoter. Already it is evident that many broken-down promoters are getting into the field with the avowed intention of profiting by the interest which has been aroused by the threat of Congressional withdrawal of radium-bearing lands in public domain, and to a lesser extent in publicity that has been given to healing properties in therapeutic uses as applied to the dreaded disease cancer. Some of us are watching with much interest the outcome of the dealings of the miner with the United States Government, where the miner takes up land in what is known as the radium-bearing areas in Colorado, and are wondering whether the Government agent knows what he has to deal with when he deals with the miner. The difficulties of checking on lots of ore, in transactions between buyer and seller, in dealing in carnotite ores from the southwestern part of Colorado, are only beginning to be known, and they are serious. What they will be when it comes to dealing with the individual miner on what the Mining Bureau calls a "reasonable basis," can only be surmised.

To people interested in the production of ores low in uranium and infinitesimally lower in the radium content it is already apparent that the effect of the activities in the field is to create artificially high value for lands, with a corresponding tendency to higher prices for the salts of radium; and on the other hand the federal authorities are getting ready to investigate

anything that savors of fraudulent misrepresentation of the facts when it comes to circularizing mine reports or putting out the inevitable prospectus. Developments through the next year will be interesting.

FORBES RICKARD.

Denver, Colorado, February 12.

Agitation at the Nevada Hills

The Editor:

Sir—I have read with interest Alfred James' annual review of the cyanide process and have gained valuable information from it. Mr. James has, however, made some deductions from published costs which are incorrect, due, I presume, to the fact that he is not familiar with the conditions under which the costs are made. For example, Mr. James compares the Nevada Hills agitation cost of \$0.85 with the three cent cost of the Hollinger and leaves the impression that the interrupted wash or change of solution during agitation, practised at the Nevada Hills, is responsible for the difference. This conclusion is not warranted by the facts, and I hope to show: first, that the change of solution is of very slight cost; second, that the Nevada Hills agitation costs are not unduly high.

As to the change of solution: this is accomplished in a Dorr thickener and is a mechanical operation precisely similar to that of counter-current decantation or continuous decantation, as it is called in the Nevada Hills cost sheet, except that one tank is used instead of three. Since the cost of decantation is given as three cents, it seems reasonable to assume that the cost of the change of solution is about one cent and could not possibly be responsible for the wide difference in question.

There are two reasons why the agitation cost at the Nevada Hills is high as compared with the Hollinger cost. The principal one is that all chemicals used in dissolving at the Nevada Hills are charged to agitation, so that the itemized cost for the month quoted reads as follows:

| | |
|-------------------------------|---------|
| Labor | \$0.105 |
| Cyanide | 0.436 |
| Lime | 0.116 |
| Lead acetate | 0.065 |
| General superintendence | 0.038 |
| Power | 0.062 |
| Total | \$0.822 |

From this it is plain that \$0.617 in chemicals alone may be deducted from the Nevada Hills agitation cost. Furthermore, the period of agitation is about forty-eight hours at the Nevada Hills, while I believe it is but five or six at the Hollinger. If this is the case, agitation costs about the same per hour at each of these mills. While the subject of the interrupted agitation is under discussion, it may be of interest to note that its effect, though difficult to determine exactly, was good, as evidenced by the fact that solutions from the first agitators after the decanting tank show a more

rapid rise in the solution values than in those before it. Also during a period when the decanter was not in use, the tailing was consistently higher than that obtained during its use.

L. B. EAMES.

Goldfield, Nevada, January 28.

Sulphide Enrichment

The Editor:

Sir—In a recent article in *Economic Geology*, Vol. VIII, p. 621, A. C. Spencer treats the chemistry of chalcocitization comprehensively. Discussing the statement of D. C. Bard, relating to the behavior of metallic sulphate solutions on calcite gangue, he cites one of his experiments in which cupric and ferrous sulphates were brought in contact with calcite, and states that calcite does not precipitate copper from such a solution. C. F. Tolman, in a recent number of the *Mining and Scientific Press*, apparently supports Mr. Spencer. Further, he doubts Mr. Bard's conclusions, for, according to his knowledge, there are many secondary enriched sulphide orebodies in limestone. Incidental to some other experiments on sulphide enrichment, I placed some ground calcite in a test tube and added some cupric and ferrous sulphate solutions of about tenth normal strength. At the end of fifteen hours iron and copper were precipitated. In the filtrate some ferrous iron was found, but no copper. I have come, therefore, to confirm Mr. Bard's conclusions. Upon the examination of the chalcopyrite and pyrite crystals placed in the same solution, distinct color changes were noted. The coating on the chalcopyrite resembled bornite and that on the pyrite, chalcopyrite. The coating was dissolved in hot hydrochloric acid, and tested for iron and copper. It showed the presence of some iron, but no traces of copper. I still hope to get some copper coating, which may take place much later than that of iron.

| Weight of buckets, pounds each | 4,700 |
| Capacity, cubic feet | 16 |
| Screen, feet | 9¾ by 50 |
| Stacker with 48-in. belt, length, feet | 115 |
| Centrifugal pumps used, inches | 14 and 16 |
| Total motor power | 1,100 |
| Weight of dredge complete, tons | 1,100 |
| Cost of dredge | \$475,000 |

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Of 2,113,080 tons of ore mined by the Utah Copper Co. during the last quarter of 1913, 91% was recovered by steam-shovels and 9% from underground work.

A dry-crushing ball-mill will discharge 20.07% on 40 mesh, as compared with 9.3% with rolls, under certain conditions and with a 22-mesh screen, according to E. H. Johnson.

Cost of development at the Nevada Hills mine, Fairview, Nevada, in 1913 was as follows: driving and cross-cutting, \$6.09; raising, \$4.94; sinking winzes, \$10.77; shaft-sinking, \$62.04; and core-drilling, \$2.58 per foot.

Transmission lines should not be stretched too tight. In December 1913 the Oriental Consolidated company, operating mines and mills in Korea, had considerable trouble through the breakage of its power wires. These were stretched too tight and broke in cold weather, necessitating slackening them in 52 places.

The transportation of black powder in metallic kegs in cars hauled by a trolley locomotive has caused more than one serious accident, the powder being ignited by a spark made from the passage of an electric current. It is bad practice to take powder and men into the mine together, or to use a trolley motor to haul a car containing powder.

Comparative tests have shown that the maximum efficiency of a centrifugal pump is attained with a lift of from 15 to 20 ft. With plunger pumps a similar efficiency is not reached until the lift is from 35 to 40 ft. After the maximum efficiency has been reached, the subsequent efficiency in the case of the centrifugal decreases with every increase of lift, whereas the efficiency of the plunger type of pump increases uniformly with the lift.

No classifying apparatus, which depends primarily on gravitational settlement for satisfactory operation, can be expected to work efficiently when the feed supply is not absolutely steady and uniform. Pulsations are often due to the operation of the pump conveying the pulp; and in the case where wet crushing is followed by sliming, it is always advisable to avoid pulp elevation as much as possible until after fine grinding is completed. Pulsations are then avoided in the classifiers, the pulp passing direct to them from the batteries. If this method is adopted there is an additional advantage accruing from the fact that wear and tear on elevating machinery is generally much less after the ore has been reground than before.

Cementing diamond-drill holes is frequently necessary. Ordinary portland cement requires from four to five days to set, and to avoid this loss of time or the expense and delay of moving the drill to another hole, rapid setting cement is sometimes used, which will permit the resumption of drilling 24 hours after the hole has been cemented. This cement, however, is so weak that it will not hold up ground which caves badly. A suitable mixture for cementing holes, which has been tried and found to possess both the advantages of strength and rapidity of setting, may be obtained by adding soda to the cement in the proportion of 1 lb. soda, 3 sacks cement, and 50 gal. water. This will set in 24 to 36 hours and will be as strong as any neat cement.

Quick hoisting is characteristic of the small lead and zinc mines of the Mississippi Valley. It is customary to hoist in buckets, or 'cans,' as they are locally termed, working without cross-heads, and occasionally even without exchange of signals between the "histerman" at the top and the "hooker" at the bottom. The hoist is set in the head-frame close to the trap-door through which the bucket comes. The engineer controls his engine with one hand, and with the other opens and closes the trap, hooks and unhooks the tail rope, dumps the bucket, and guides it back to the shaft. Working in this fashion, 1035 cans, weighing 1000 lb., have been hoisted from a depth of 275 ft. in an 8-hour shift, using a small first-motion steam-engine. With an electric hoist at the Diplomat mine, in the Joplin district, 1031 buckets were hoisted in a 9-hour shift from a depth of 200 ft. At this mine 5848 buckets were hoisted in 6 shifts.

Concreting stamp dies in a mortar-box has been done with satisfactory results by Chester L. Proebstel, of Yreka, California, during the past 18 months. The die is first placed on the ordinary cushion of sand and then a concrete of 40% portland cement and 60% clean quartz sand is used, filling the space around the dies up to the under side of the chuck-block. The concrete is put in medium wet, well tamped, and allowed to set for several days. This will probably seem to be a loss of time, but is about equaled by the increased capacity and time saved in cleaning-up during the life of the die. As the die wears away, the concrete also wears, and at about the same rate. No difficulty is experienced in removing the worn out dies, as the concrete is practically gone at the same time. The wear of the concrete when properly put in is fairly uniform, and comes toward the centre of the die, thus tending to throw all pulp on to the die with each return splash. There are several advantages to be gained in this arrangement: 1. better inside amalgamation is insured, as all loose amalgam and quicksilver is kept up near the inside plates; 2. during a clean-up the amount of battery sand is small; (3) dies are not removed at monthly or semi-monthly clean-ups, and 4. there is no danger of dies bouncing or moving.

GUADALAJARA, JALISCO

SCARCITY OF SILVER COIN IN MEXICO.—BANKING AND HARDSHIPS OF MINING COMPANIES.—EXPORTS OF ORE AND CONCENTRATE.—CINCO MINAS AND EL FAVOR.

The Mexican government is now coining large quantities of *tostones* (50-centavo pieces) in an effort to relieve the difficult situation that has resulted from the hoarding of silver and the consequent shortage of coin for business operations. A call was made on the Sociedad Afinadora de Metales, the French refining concern of Mexico City, for 4 tons of silver per day for a period of 50 days, but as the silver bullion shipped to Mexico City amounts to only $2\frac{1}{2}$ tons per

product of the Real del Monte Co. of Pachuca, a subsidiary of the United States Smelting, Refining & Mining Co., and at present the largest producer of silver in Mexico.

A number of mining companies have funds tied up in the Bank of London & Mexico, which is paying no more than \$200 weekly on each checking account at its main bank and branches, and have been forced to provide additional funds for new accounts in other banks. It is reported that some of the larger companies received information that the bank planned to restrict payments shortly before it closed temporarily, and it is said that the El Oro Mining & Railway Co. drew out \$250,000 in one check. It is understood that the negotiations with London bankers for a loan of £800,000 for the Bank of London & Mexico have fallen through. Officials of the finance department have held conferences with representatives of mining companies, in connection with plans for reforming the present mining law so as to facilitate the exportation of ores and mill products ordinarily handled by

GUERRERO MILL OF THE REAL DEL MONTE Y PACHUCA COMPANY.

This plant has a capacity of 300 tons per day and cost \$800,000. It consists of 40 stamps crushing through 4-mesh screens, 8 Evans-Waddell Chilean mills, Wilfley and Johnston tables, Dorr classifiers, Abbé tube-mills, Callow cones, agitation apparatus for slime, a decantation and Butters filter plant, and precipitation on zinc shaving. The Loreto mill, operated by this Company, has a capacity of 300 tons per day. It consists of jaw-crushers, 14 Chilean mills crushing through 40-mesh screen, also 40 stamps, Wilfley and Johnston tables, Dorr classifiers, Abbé and Krupp tube-mills, agitation of slime with cyanide, decantation and Butters filter plant. Costs at the mills are from \$8 to \$10 per ton. Power is supplied at \$96 per horse-power year.

day, the Sociedad Afinadora has been unable to fill completely the government's order. The silver is being purchased at a rate of \$50 per kilogram. The government has agreed to deliver to the companies supplying the silver \$85,000 in 50-centavo pieces weekly, this amount being more than sufficient for payroll requirements. For some time mining companies in many states have been forced to pay premiums for silver coin needed for their payrolls, and in some instances much difficulty has been experienced in securing adequate supplies. The companies shipping to Mexico City at first arranged to deliver a certain amount of silver and receive the equivalent in silver coin, less expenses of assaying and coining, but later the government decided to purchase the bullion through the Sociedad Afinadora, and that concern will pay for it in foreign drafts. Of the $2\frac{1}{2}$ tons of silver daily marketed through the Sociedad Afinadora, 1 ton is the

the smelters of the country. The plans are due to the fact that the majority of the smelters have been forced to close. Export shipments of ore now are being made through Vera Cruz by concerns operating in Oaxaca and the state of Mexico, and the Amparo Mining Co., a Jalisco concern, is shipping its concentrate through Manzanillo to the Selby smelter in California.

The big reduction plant of the Cinco Minas Co., of New York, at the Cinco Minas, in the Hostotipaquillo district of Jalisco, has been placed in commission, and the 30 stamps are dropping steadily. It is expected that the mill soon will be handling 300 short tons of ore per day. A large tonnage of ore is already blocked out in the mine, and extensive development is being resumed. The Cinco Minas mill was built under the direction of Godfrey D. Doveton, who died recently in Guadalajara as the result of injuries received

at Cinco Minas when his right arm was caught in a belt-conveyor and terribly torn. The addition to the El Favor mill in the Hostotipaquillo district, consisting of 15 stamps, 2 tube-mills, concentrators, and cyanide annex, is in operation, treating principally ore from the Mololoa mine, which, like El Favor, is a Makeever property. In the original El Favor 20-stamp mill an increased tonnage of El Favor ores now is being handled, and the Company is doing some custom work. The acceptance of custom ores is promoting development in the Hostotipaquillo district. Construction work on the reduction plant at the Casados mine in that district is nearing completion, and it is expected to have the plant in readiness for operation by next May. From 75 to 100 tons will be handled daily. In a small experimental plant now in operation at the Casados, an extraction of 85% is being obtained. Shipments of high-grade ore from Casados continue at the rate of two carloads per month.

LONDON

ARGUMENT IN FLOTATION PROCESSES, AND COMPOSITION OF THE COURT.—ENGLISH INTERESTS IN ONTARIO, AND NEW COMPANIES.

As I mentioned in December, the flotation appeal to the Judicial Committee of the Privy Council was ordered to be re-argued before a fuller court. The whole of the week ended January 31 was occupied by this rehearing, and judgment has been reserved. It will be remembered that the appeal was lodged by Elmores against the judgment of the New South Wales court, which held that the Minerals Separation process, as used by the Sulphide Corporation at Broken Hill, was not an infringement of the Elmore acid patent of 1901. The court that heard the appeal in December was composed of Lords Dunedin, Moulton, and Shaw, and as I pointed out at the time, the last two had sat on the English case. Whatever the reason, the Lord Chancellor ordered a re-argument before five judges, and the court consisted of the Lord Chancellor and Lords Parker, Sumner, Parmoor, and Dunedin. It will be noted that Lords Shaw and Moulton retired from the case. Of these five judges, the Lord Chancellor, otherwise Lord Haldane, is a lawyer of unusually wide interests, from education to the army. His quick trip to America and back is sufficiently recent for readers to remember it. Parker and Sumner are judges that have much to do with patent law, and, curiously enough, before they were elevated to the bench, had been engaged as counsel in flotation litigation, though not in connection with the validity of patents. Parmoor used to be Sir Alfred Cripps. All these judges are men of high attainments, who have won their way by their abilities, not pitchforked into their positions for political services rendered to their parties. Altogether it is a notable court, though naturally no individual member knows anything about ore dressing. But as Sir Joseph Porter used to say in the opera: "It is one of the glories of this great and happy country that the judges never know anything about the matter in hand." In this way they differ from the editors of technical papers. Nevertheless, this court has a shrewd idea that Elmore was the first to mention the function of acid in assisting the selective action of oil for metallic surfaces. It would not surprise me if they reversed the Australian judgment.

At the present time, Canadian ore deposits are receiving a large share of attention among London speculators. The two Cobalt companies controlled in London by Rose & Van Cutsen, and in Canada by Parker and Watson, namely, the Cobalt Townsite and Casey Cobalt, are doing so well that English investors are for the first time feeling that they are getting something from Cobalt. Interest in Porcupine has mostly disappeared. There is a boom at present in connection with Kirkland Lake properties. A great quantity of advertisements are being circulated by the Kirkland Lake

Proprietary, which is run by H. G. Latilla, hitherto connected chiefly with Rhodesia, where he worked in conjunction with Sir Abe Bailey. One of the weekly papers made an onslaught on Mr. Latilla and his new promotion, alleging that all the companies in his office were bogus ones. This was a serious accusation, but Mr. Latilla has passed it by with a pleasant account of the large amount of business his companies have done. The Kirkland Lake Proprietary will form a subsidiary company to acquire the Tough-Oakes property, directly Clement Foster arrives in this country with the necessary deeds. The Company has also bought or has options on the whole of the capital of the Sylvanite, and has a similar option on 64% of the Teck-Hughes. In addition, it has options on 51% of the Burnside claims and 78% on the Gull Lake. The report by H. H. Johnson on the Kirkland Lake district is not immune from criticism from the technological point of view. In many quarters this promotion is not popular. Nevertheless, I ought to say that a financial group of excellent standing, L. Ehrlich & Co., taking their advice from an eminent geologist who has visited the district, has become enthusiastic.

Another company is the Kirkland Lake Exploration, formed by the Anglo-Spanish Trust. The latter Company is a private enterprise, and its constitution and objects are unknown, except to those who have time to search the records at Somerset House and elsewhere. The promoters appear to be a firm of stockbrokers, Wheeler, Cornwallis West & Co., of Pinner's Hall. The prospectus as advertised asks for £50,000 cash wherewith to explore and hunt for mines. Particular interest attaches to this promotion because F. H. Hatch, the eminent geologist, is on the board of directors and was advertised as having a call on shares. Naturally, mining engineers objected to Mr. Hatch becoming associated with Stock Exchange gambles in this way, and a few days after the issue of the prospectus he publicly renounced his call, and was appointed to the position of consulting engineer to the Company. He has left for Kirkland Lake, and no doubt his geological knowledge will be of immense value, not necessarily to the Company, but to the world at large.

VICTORIA, BRITISH COLUMBIA

PORTLAND CANAL DISTRICT, WORK OF THE TUNNEL COMPANY, AND PROSPECTS OF OTHER PROPERTIES.—LILLOOET DISTRICT.—CORONATION AND WHY NOT COMPANIES.

The latest reports from the Portland Canal district state that the long cross-cut adit, which the Portland Canal Tunnels Co., Ltd., has been driving for the past year, to prove whether the orebodies on the Glacier creek and Portland Canal groups of claims maintain their continuity to any great depths, has been driven 2830 ft., and has passed through two crushed zones, in each of which a little ore was found. Driving on both of these zones has been carried on for a while, resulting, it is now said, in exposing a body of better grade ore, but only about 6 in. thick. This is in the Glacier Creek group and at a vertical depth below the old workings on that property about 2000 ft. At the present time this is the only work being done in the Portland Canal district. The other companies, of which there were 12 or 15 working in 1910, have suspended operations, apparently waiting for the results of the Tunnel company. W. J. Elmendorf, formerly of Spokane, is the manager for the company, and it is on his advice that this long adit has been driven. In 1910 there was such a boom in this district that mining stocks of some of the companies were selling readily on the local exchanges at above par; but the results from operations during that and the succeeding years have been so disappointing that naturally the stocks have slumped. It is predicted that if further driving continues to develop orebodies of commercial grade, the camp will revive and probably another boom occur.

During the present winter, work has been carried on by the Coronation Mining Co., on Cadwallader creek, and the Why Not Syndicate, on Bridge river, in the Lillooet district. The former Company has been sinking on the Little Joe claim, below the No. 4 level, and at last reports had reached a depth of about 60 ft., having followed profitable ore all the way. This winze was started near the western end of the shoot in the Little Joe vein, the length of which pay-shoot on the No. 4 and upper levels has ranged from about 350 ft. to nearly 700 ft., the greatest length being found on the No. 1 and 2 levels. A pump is now being installed, and the Company proposes to continue sinking as deep as can be handled with windlass, then drive east along the vein. I am informed that, should the development work prove as satisfactory as it promises to, from the results obtained from assays of the ore taken from the winze, machinery will be installed to do deeper development on a systematic plan. Last year the ore milled from the vein between No. 3 and 4 levels averaged about \$33 per ton in free gold, and the concentrate saved by blankets averaged 4% and contained \$150 per ton. The Why Not Syndicate has been driving on the main orebody, the drift being now in 180 ft. Cross-cutting from the end of this drift has been started, in the expectation of cutting another orebody, which shows outcrops paralleling the vein

SURFACE VIEW OF LITTLE JOE CLAIM.

on which the drift has been run. If the gold content in the main vein averages not less than \$8 per ton, operations can be carried on profitably on this property, as the facilities for mining, transporting the ore to the millsite, and milling with water power are extremely favorable for working at a minimum cost. The other properties on Cadwallader creek and Bridge river, although idle during the present winter, will be actively worked during the summer. In fact, it is expected that operations will be resumed on the Pioneer and Lorne groups of claims, early in the spring. In this district the snow is usually all off early in April.

The Copper River coalfields are situated on the Copper river, west of the Bulkley valley, about 30 miles from the new town of Smithers on the Grand Trunk Pacific railroad. Recently the firm of Aldous & Murray, Limited, of Vancouver, secured an option on the coalfields, and shipped a diamond-drill, with other machinery and supplies, to the property. It is reported that a wagon-road has just been constructed to connect this property with Smithers, about 30 miles distant. This machinery will be transported over it at an early date, and drilling operations begun to test at depth the various seams of coal that underlie these fields, which are reported to cover 16,000 acres. There are said to be six seams of coal on the property, and the main one is said to average 12,500

tons per acre. The owners of this coalfield are the National Finance Co., of Vancouver, and it is from that Company that Aldous & Murray have secured an option, but in whose interests is not yet known, although because of the close connection between that firm and the Grand Trunk Pacific railroad, it is considered likely that they are acting for the railroad company. This, however, is only a conjecture caused from the fact that Aldous & Murray have been right-of-way agents for the railway, and they now have the exclusive sale of the Grand Trunk Pacific townsite of Smithers.

NEW YORK

FINANCING BRITISH COLUMBIA COPPER, BRADEN COPPER, INTERNATIONAL SMELTING & REFINING, AND INTERNATIONAL AGRICULTURAL CHEMICAL COMPANIES.—AMERICAN INSTITUTE OF MINING ENGINEERS MEET.

The improved state of the money market is already beginning to exhibit itself in new financing of mining companies already under way, or merely proposed. I have already referred to the proposals for Inspiration and British Columbia. The full details of the British Columbia plan have now been given out and involve the creation of a new company, the Canadian Copper Corporation, Ltd., with an authorized capital of \$5,000,000 in \$5 shares, and with \$1,000,000 in 10 year 6% convertible bonds. Hayden, Stone & Co. have underwritten \$600,000 of the bond issue, and such is the magic of a name that when this fact was announced British Columbia shares made a sharp advance. The debentures will carry with them *pro rata* stock in the Company, and Hayden, Stone also have an option on the remaining \$400,000 in debentures and 200,000 shares. This entire scheme depends on the exchange of over 51% of the stock of the British Columbia Copper Co. before March 15.

The rumors that have been current for many months that Braden would have to do some new financing are taking more definite form. Braden has an authorized bond issue totaling \$8,000,000, divided into \$4,000,000 6% first collateral trusts, all outstanding, \$2,000,000 7% second collateral trusts, \$1,000,000 outstanding, and \$2,000,000 7% three year convertible debentures, all outstanding. Authorized stock issue totals \$14,000,000 of which \$6,000,000 is outstanding, \$7,000,000 is held in the treasury against the conversion of bonds, and \$1,000,000 held in reserve against the \$1,000,000 remainder of the second lien 7's, authorized but unissued. The earnings of the Company are now substantially in excess of its present bond charges. No definite statement as to what form the new financing will take has yet been made. Another company which is expected to do some new financing is the International Smelting & Refining Co., which has undertaken to build the smelter at Miami to treat the Inspiration and Miami concentration. Although not exactly a mining company, the International Agricultural Chemical Co. has a good deal of interest from a mining standpoint, since its raw materials are largely the product of mining or smelting. The Company has been carrying a floating debt of \$4,825,000 representing its growth and expansion in the past two years. This will be taken care of by a new issue of 5% debentures. The first mortgage 5% issue of 1928 under which two separate pieces of financing have already been accomplished has now been closed and no prior obligations can be put ahead of the new \$7,000,000 bonds. With this financing, American Agricultural will have \$17,000,000 bonds, \$27,000,000 preferred, and \$18,330,000 common; or \$45,000,000 of stock paying dividends as an equity behind its bonds.

Details of the earlier sessions of the American Institute meeting held in this city last week are given on another page. The sessions of Wednesday and Thursday, however, were no less interesting.

The number of papers to be presented was so great that it

was necessary to hold simultaneous sessions in adjoining rooms. In one room the papers on mining law were the topic for discussion. H. V. Winchell was to have presided over this session, but was unable to arrive in time because of a late train, and J. A. Holmes presided. The first paper was 'The Disposition of Natural Resources,' by G. O. Smith, presented in abstract by the author. Dr. Raymond announced that he had submitted discussion of this for publication, but brought out a few important facts. The next paper was 'Should the Apex Law be Now Repealed,' by C. H. Shamel, which was read in abstract in the absence of the author. This was vigorously criticised by Dr. Raymond, who pointed out that the law of 1872 was not the outgrowth of "immemorial custom," but was rather the product of a few years of local experience, and ridiculed the method of determining the amount of litigation caused by the apex law used by Mr. Shamel, since a suit which directly arose from an apex question might be attacked and defended on twenty different technical points, though the apex question was the sole originating cause, illustrating his argument by actual cases. But he chiefly objected to the proposal to have questions of fact decided by the U. S. Geological Survey, and not subject to review by the courts. Thomas J. Walsh, U. S. Senator from Montana and chairman of the Senate Committee on Mines and Mining, argued in a similar vein; citing cases from his experience in Montana. This led naturally up to the next paper, 'The Apex Law in the Drumlunnon Controversy,' by C. W. Goodale, appearing on another page, which was read in abstract in the absence of the author. The account of the famous controversy was supplemented by Dr. Raymond, who was connected with the case in the beginning, and by Senator Walsh, who was one of the attorneys in its concluding stages twenty years later. M. K. Rodgers told of some of the difficulties of the apex law according to his wide experience and stated that he would advise a client to invest in property in Canada or Mexico, rather than in the United States, since revolutions in Mexico only damaged a property, whereas in the United States it might be lost altogether. He also told of the admirable foresight of a Swede whose claims in Alaska fairly bristled with stakes. When asked why his claim appeared to have been 'jumped' so often, he replied, "I yump him myself every six weeks."

Next a paper on 'Classification of the Public Lands' was presented in oral abstract by George Otis Smith. An article by F. F. Sharpless on the 'Segregation and Classification of the Natural Resources of the Public Domain' was passed over, in the absence of the author. A paper on 'The Initiation of Title to Mineral Land,' by Albert Burch was read by G. O. Smith, and another on 'Good Ideas in the Mining Laws of British Columbia and Mexico,' by F. L. Sizer was read by T. T. Read. At the afternoon session, H. V. Winchell presided and read his paper, 'Why the Mining Laws Should be Revised.' This was followed by 'Mining Law Revision: How to Obtain it,' by E. B. Kirby. Senator Walsh then gave the review of the present status of mining legislation at Washington which is elsewhere reproduced. The ensuing general discussion brought out the views of the many important mining men present and made especially clear the necessity that the new code of mining laws should be drafted by experienced mining men who are also familiar with the law. In the adjoining room a session on iron and steel was held. The sessions for the day were concluded by an illustrated lecture on the mining of bituminous coal, by Samuel A. Taylor.

In the evening the annual dinner was held at the Waldorf-Astoria, the same place as last year. The attendance was unexpectedly large and over 200 members, their wives, and guests had been crowded into the dining room, a number of late comers had to be turned away. At the close of an excellent dinner the retiring president, C. F. Rand, with characteristic modesty made a speech attributing the good

results of the year to everyone else except himself. At its conclusion W. L. Saunders, the toastmaster, asked anybody present who had not been mentioned to hold up his hand, which evoked much applause but no hands. The new president, B. B. Thayer, was then introduced and in a brief, businesslike speech pointed out that Mr. Rand had given largely of time and effort to the upbuilding of the Institute, and that his ability to evoke enthusiasm in others was only a part of what he had done. Mr. Thayer was followed by Thomas J. Walsh, senator from Montana, who praised the mining engineer for his contribution to civilization. Thomas B. Stearns then spoke of the glories of Colorado, and was followed by W. A. Clark, ex-senator from Montana, who spoke of early days in mining education in this country and paid a tribute to Dr. Raymond, who spoke next and was somewhat pessimistic as to whether the new broom of enthusiasm in the Institute would continue to sweep clean. The concluding speaker was D. M. Riordan who spoke in his usual vein.

On Thursday simultaneous sessions were again held. In the geological session the depth to which underground waters extend was first discussed. The topic was opened by a paper by A. C. Lane and was afterward discussed by J. F. Kemp, F. L. Ransome, L. C. Graton, E. C. Bastin, T. T. Read, and J. D. Irving. The next topic was the question as to what extent chalcocite is primary and to what extent a secondary mineral. The topic was presented by L. C. Graton and was discussed by J. D. Irving, T. T. Read, W. Lindgren, and F. L. Ransome. The third topic taken up was the discussion of the garnet zones produced by igneous intrusions. This was discussed by Waldemar Lindgren and, in a written paper, by C. K. Leith. Meanwhile in the adjoining room the oil and gas session was dealing with an even more interesting list of papers. The afternoon session was almost devoted to E. Coste, who first presented in abstract the paper by A. Adiasewich on the Russian Oil Fields, and then defended vigorously his own theory of the formation of petroleum deposits. S. S. Wyer discussed the proposal to make natural gas lines common carriers and M. W. Ball discussed the placer law as applied to oil. R. M. Catlin and F. M. Anderson discussed the occurrence of oil shales at Elko, Nevada, where the oil cannot be extracted by solvents, only by distillation. The session was concluded by a most interesting paper by I. N. Knapp on oil and gas sands, illustrated by excellent lantern slides. There was to have been a session in the afternoon to discuss papers on precious or base metals. The first paper, by C. R. Hayward, was presented in abstract by H. O. Hofman, and Robert Linton presented his interesting paper on cyaniding silver ores in Mexico, but none of the authors of the eight other papers on the program were in attendance, and the session adjourned. This was the sole defect of what was otherwise one of the best meetings the Institute has held, and it is to be regretted that authors who have contributed important papers should not be on hand to present them and to answer questions.

Last week was an extraordinarily dull one, as far as mining news is concerned. Possibly all the mining men were attending the meeting of the American Institute of Mining Engineers, and had no news to give out, or it may have been the weather, which piled one snowfall on another, blocking the streets and hampering everybody in the conduct of business. Interest centres on what will happen in Mexico, now that one of the bandits who poses as a patriot leader has been so unwise as to shoot an Englishman. As a result, the attitude of 'watchful waiting' has received a severe jar and everyone is speculating on what the outcome will be. The ferocity and insolence of the atrocious act has aroused general resentment, but scarcely to the point of a general demand for intervention. The copper market has fallen flat and little business has been done. Even the export sales failed and the week closed with everybody awaiting developments.

General Mining News

ALASKA

BETHEL

An option and bond on the Royal group of 14 quartz claims, and the Golden Gate valley placer property of 1000 acres, has been given to New York people by H. W. Reeth.

FAIRBANKS

The Newsboy mill crushed 400 tons in January, recovering \$11.25 per ton, with a profit of \$500. The whole length of Cleary creek is active, with shaft-sinking, taking out dumps, and getting ready for next season. At 1 Below, Hilty & Co. are finishing the bedrock drain, 1900 ft. long, after a year's work. It is 3 to 5 ft. wide inside timbers, and 35 ft. deep. Adjoining claims will benefit by the drain. Ivy & Co. are digging a drain to connect with Hilty's. DuBerry and Fuller have helped with the Hilty drain and are ready to hoist gravel. Work on 3 Below is to be resumed by Cunningham, Morrison, and Rasmussen. A dump of fair size has been taken out from the old Boone by Woods and Piper. Shafts are being sunk on 6 Below by Johnson and Pearson. Lalu, Black, and Mitchell are taking out good 'pay' from 7 Below. A large dump is on 8 Below, owned by Nars, Hansen, and Jorgenson. Work is to be started on 9, 10, and 11 Below in May.

JUNEAU

The Alaska Mexican, Alaska Treadwell, and Alaska United companies have declared dividends of 20c., \$1, and 30c. per share, respectively, payable at San Francisco on February 28.

NELCHINA

On bedrock, 14 ft. deep, G. A. White has found gravel worth \$1.50 per square foot, at 16 Above Flat creek. Four feet of gravel will yield from 1 to 40 cents per pan. A new deposit has been discovered 18 miles from Flat creek, and the prospectors have 18 in. of gravel giving from 15c. to \$1 per pan. Fairbanks men have bonded claims for \$90,000 on Crooked creek. A Keystone drill will be used next summer. There are about 300 men and 4 women in the camp at 16 Above, Flat creek. The winter has been fine, the coldest day being 42° below zero, little wind, and 30 in. of snow.

ARIZONA

GREENLEE COUNTY

The directors of the Arizona Copper Co., Ltd., report that after carrying to reserve \$34,415, in terms of the agreement with the debenture holders, and \$45,585 for capital expenditure, the surplus for the year ended September 30, 1913, in-

CAVED SQUARE-SET STOPE, ARIZONA COPPER CO.'S MINE.

cluding \$39,261 brought forward, is £246,911. Deducting preferential dividends amounting to £24,531, the sum of £222,380

is left, out of which the directors recommend a dividend for the year of 66c. per share, free of tax; of this amount of dividend 36c. per share was paid in July last. The dividend absorbs £208,986, and the balance of £13,394 will be carried forward. The Company has ordered a 150-kw., 250-volt, synchronous converter, three 60-kva. transformers, and switch-board panels from the General Electric Company.

CALIFORNIA

AMADOR COUNTY

The South Eureka Mining Co. has paid another dividend, making \$41,998 for the current year.

BUTTE COUNTY

A fine diamond was found recently by a prospector in placer ground at Cherokee. He sold it to an Oroville jeweler for \$100. Over 250 stones have been found in this district to date. The old Magalia or Pershbaker drift gravel mine in the Magalia district, will probably be opened by driving a long drift to drain the old workings.

CALAVERAS COUNTY

The Hamby mine, near Mokelumne Hill, which has been worked in a desultory fashion for 10 years, is being unwatered. Prospects are good, and there is a good hoist and mill on the property. L. Everett is superintendent.

NEVADA COUNTY

Rich gold ore is being extracted from the Premier mine, north of Grass Valley. Jesse R. Butler is superintendent.

On February 22, a cross-cut in the Golden Center mine, Grass Valley, cut 30 in. of rich gold-bearing ore, which was highly mineralized. It was found 300 ft. from the shaft, and gives 400 ft. of backs. Leyner drills are used in development work.

PLACER COUNTY

Nevada people have acquired the Little Banner mine, on the American river, one mile from Auburn, for \$25,000. A 300-ft. adit has been driven to cut the vein, and a fair tonnage has been proved. The Rawhide mine, on the north fork of the American river, six miles from Towle, is being worked again by J. L. Bryson, under lease from the Helester Gold Mining Company.

PLUMAS COUNTY

Good ore has been opened in the San Jose mine, near Seneca.

SHASTA COUNTY

The Mt. Bally Mining Co. is to erect a small mill on its West End mine near Stella. Kennett people are mostly interested, and Briceland Blair is manager. The Gladstone company, near French Gulch, has paid another dividend of \$9000, making \$18,000 for this year.

SISKIYOU COUNTY

The mine and mill of the Gold Run, at Gilta, are being worked full time with 15 men. R. W. Bender is superintendent.

SAN DIEGO COUNTY

The Montezuma mine consists of 18 claims covering 360 acres in the San Ysidro range, 11 miles from Warner's Springs, and over \$100,000 has been spent in development. Regular work started in January 1911, and 3255 ft. has been opened in the Morning Star and Eureka claims, and 599 ft. in three other claims. Eight ore-shoots have been opened in the two claims mentioned, giving a high average in gold, silver, lead, and copper. The main shaft is being sunk to 250 ft., where it is intended to drive 1000 ft. No. 2 drift is in 941 ft. The shoots are up to 160 ft. apart at this level. In September 1913 the shaft-house and equipment was destroyed by fire, a loss of \$5355. This has been renewed by a larger plant. A 5-stamp mill and concentrator has been in operation, but a cyanide plant is necessary. David McGregor is superintendent.

TRINITY COUNTY

On February 18, Frank Schlomberg sold 14 placer claims on the north fork of Coffee creek, 16 miles from Trinity Center, to W. H. McEwen, who recently bought the Mad Ox mine near Whiskeytown. The late owner has worked one giant for a considerable time. The gravel is said to amount to 500,000 cu. yd., worth up to 50c. in gold.

TULUMINE COUNTY

(Special Correspondence.)—The Jamestown Exploration Co., which is operating the Carlin mine, near Jamestown, has elected a new board of directors composed of C. L. Six, L. T. Freitas, A. R. Kirkland, W. S. Kelly, and J. H. Utt, and will establish its principal office at Stockton. It is understood that the Company will in the future make a weekly report to the stockholders. The Plummer brothers, of Columbia, have been recovering a good deal of gold from a new prospect on the Caverone ranch, four miles east of Columbia. Outcrops of the vein contained coarse gold, and the lucky finders realized several hundred dollars during the first few days. Prospects for further gold returns are said to be decidedly good. The Sugarman mine, on Bald mountain, north of Sonora, has been producing a large quantity of gold during the past few weeks, but how much has been extracted cannot be learned, though it is said to amount to several thousand dollars. The mine is worked by Charles Smith and Robert Watson. The Wilson & Means 'pocket' mine, on Jackass hill, near Tuttletown, is again yielding gold for Charles and James Gillis and H. Bowerman, who have been working the property for a number of years. Since the find was made a few days ago, over \$10,000 has been recovered, and it is believed that when a thorough clean-up has been made, that sum will have been considerably increased. Probably not until the latter part of March will complete milling operations be resumed at the Shawmut. Meanwhile repair work and improvements which have been in progress for some time will be finished.

Sonora, February 21.

YUBA COUNTY

Good gravel has been opened in the Orient drift-gravel mine in the Camptonville district. John E. Lasslett is superintendent for the lessee, W. H. Hood.

COLORADO

EAGLE COUNTY

There is nothing new regarding the alleged discovery of rich carnotite ore in the Dakota mine, near Eagle. Silver ore is being transported from the Lady Belle mine to the cars at Eagle on sleds. The road to the North Dakota and Best Chance is in bad condition. Mines on the Salt Creek side of the mountain are opening excellently.

FREMONT COUNTY

A wagon-load of ore, assaying 34% lead, 41½% copper, 32 oz. silver, 0.11 oz. gold, with uranium and vanadium content, has been sent to the Pueblo smelter from the Oak Creek district, 15 to 20 miles west of Canon City. The ore was brought in by E. C. Metz. Considerable excitement prevails in Canon City.

GUNNISON COUNTY

The Glacier Mining Co., which has recently been organized and which is operating the Star and Independent mines on Italian mountain, has taken a bond and lease for \$25,000 on the mining claims on Italian mountain which was owned by the late Howard Marshall. The mill is working at the Iron Cap, near Spencer, and mine men are working under A. McFarlane.

LAKE COUNTY (LEADVILLE)

Storms have interfered with regular work in the district. The present outlook for increased activity is good. The Leadville district mill is working steadily and producing 60

tons of zinc concentrate per day. Residue from the old Adams mill containing 18 to 20% zinc, is being concentrated to 40 and 45% zinc. Retimbering the Moyer shaft of the Iron Silver Mining Co. is nearly finished. Five furnaces are working at the Arkansas Valley plant.

OURAY COUNTY

The report of the manager of the Mountain Top mine, G. H. Barnhart, states that the main north drift is 967 ft. long. The first ore-shoot was 326 ft. long, and 6 to 48 in. wide, and the paystreak averaged gold 0.153 oz., and silver, 44.47 oz. per ton. The lead content will average 5%. At 560 ft. north of this shoot, another was cut, which was profitable for 210 ft. The paystreak was from 12 to 36 in. wide, averaging 13.37% lead, 0.047 oz. gold, and 34.45 oz. silver. About 890 ft. north, the foot-wall side of the drift opened the Big Spar vein, resulting in a heavy flow of water. The vein showed no mineralization. Work on No. 6 level and in the main raise is promising. The Company's Morning Star mill-site is at Cañon and Blythe creeks, and safe from snow-slides. A better site is west of the Atlas mill, and near the upper terminal of the proposed Ouray-Sneffels tramway. Surveys have been made for tramways from the Mountain Top-Sunrise adit to these sites. The respective lengths and falls are 4956 ft. and 1040 ft., and 5400 ft. and 1070 ft. The flotation process in the Atlas mill works satisfactorily, and as the Mountain Top ore is similar, the process may suit. Tests on ore from the Humboldt mine gave over 90% of the lead and silver by flotation.

PUEBLO COUNTY

The Smuggler Leasing Co., at Aspen, has ordered two 125-hp. motors and a switchboard panel from the General Electric Company.

TELLER COUNTY (CRIPPLE CREEK)

A total of 2750 men are employed in the mines, mills, samplers, and smelters connected with the Cripple Creek district, according to *The Cripple Creek Times*. This number does not include men employed by ore-hauling contractors. It is expected that 18 lessees will be working at the Golden Cycle mine in a few days. The Gold King Mining Co.'s annual report shows that the lessee of the mine, Owen Roberts, shipped 4038 tons of ore, worth \$57,155, from which the Company's royalty was \$14,817. A dividend of \$9368 was paid, equal to 1c. per share on 936,850 shares. The cash balance on hand is \$55,291. The total production to date is 95,492 tons, yielding \$1,924,971.

IDAHO

BLAINE COUNTY

Work is to be resumed at the Independence mine and mill by Harry J. Allen, managing owner, and about 30 men. All litigation in connection with the property is finished. It is reported that a snowslide has either destroyed or covered the mill, power-house, boarding and bunk houses, and other equipment of the El Oro mine, on Bear creek, 70 miles from Hailey.

IDAHO COUNTY

In an adit being driven on a vein in the Black Pine mine, two miles from Elk City, rich gold ore has been opened on the hanging wall. Frank Peck has also opened \$100 ore in the Oro Grande district, between 300 and 400 ft. Several thousand tons of \$12 to \$15 ore is blocked out in the Colonel Sellers, owned by Mrs. Parr. The Elk City district is fairly active just now.

SHOSHONE COUNTY

Although cut about a month ago, an official announcement of the opening of 8 ft. of lead ore in the Success mine, near Wallace, has only just been made. This property is fully equipped with a mill, and paid \$90,000 in dividends in 1913. H. F. Samuels is general manager. A large low-grade ore-body has been developed in the Star mine, adjoining the

Morning, and it is likely that the Federal company will buy the property, the present bond calling for \$750,000. The Hecla Mining Co., operating at Burke, has paid dividend No. 128, of 2c. per share, amounting to \$20,000. The motors running in and out of the Kellogg tunnel at the Bunker Hill & Sullivan mine will be operated in the near future by a block signal system now being installed. The 'safety first' policy at this property shows a reduction in the number of accidents during the past six months. Across the track near the Kellogg tunnel is a large sign, 'Safety First,' in electric lights. Following this policy, the Company is doing away with trolley wires in the mine, except in the Kellogg tunnel, having installed electric storage-battery locomotives. The third one of these locomotives, weighing eight tons, was put into service this week. One of these has been at work for

15,357 tons, returning \$66,399, showing a loss of \$7100. The surplus on January 1 was \$60,569.

NEVADA

ELKO COUNTY

In spite of bad weather and its isolated position, mining at Contact is being pushed along. The Seattle-Contact company is shipping high-grade copper ore. The Antelope mine has been opened by three 40-ft. shafts and drifts, and good ore is extracted.

The deputy state mine inspector, James W. Gaughan, reports that the camp of Bullion is a promising one. Both the Nevada Bunker Hill and Bullion Nevada companies have driven adits, which will be timbered and the ventilation improved.

ESMERALDA COUNTY

The annual report of the Florence Goldfield Mining Co., H. B. Clapp superintendent, contains the following information: During 1913, 4307 tons of ore was mined, and 3159 tons treated at the Jumbo Reduction Co.'s plant at Bonnie Claire, which is leased to the Florence company. The yield was \$9.11 per ton, with 86% recovery. The lease of this plant was discontinued by previous arrangement, and since November 988 tons of ore, worth \$12.22 per ton, was sent to the Western Ore Purchasing Co. and the Belmont Milling Co. The year's revenue was \$41,979, and expenses \$85,987. Cash on hand at the beginning of 1914 was \$11,191. Development covered

2324 ft., at a cost of \$4.64 per foot. Work at 800, 1000, and 1200 ft. was unprofitable, and has been stopped. The orebodies are irregular and ore reserves cannot be estimated. The upper levels should add considerably to the available ore. At present, the monthly output is from 700 to 1000 tons.

A 5-stamp mill is now working in the Diamondfield portion of the Goldfield district. It is at present crushing ore from dumps on leases held by the Diamondfield M. & M. Co. A mineralized vein has been cut at 735 ft. in the Oro shaft. The water has also increased. T. F. Manning is manager.

During January, the Goldfield Consolidated mill produced a net realization of \$164,914 from 30,198 tons of ore. Costs totaled \$5.85 per ton, of which mining was \$3.25 and treatment \$1.75 per ton. Development covered 2666 ft. at a cost of \$4.91 per foot. There was nothing of special note from this work, but the stopes are looking better than for three months past.

HUMBOLDT COUNTY

With a capital of \$100,000, the Winnemucca Milling & Ore Purchasing Co. has been formed. W. G. Adamson, John R. Turner, of Winnemucca, and H. J. Murrish, of Lovelocks, are principally interested. A mill is to be built and custom work done.

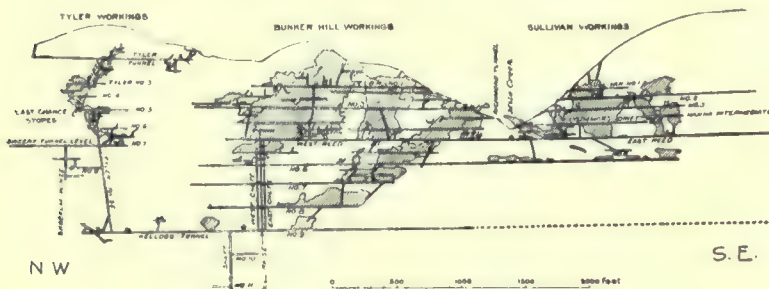

LANDER COUNTY

Placer mining in the Battle Mountain district is increasing, especially in Copper cañon, Eldorado cañon, Copper basin, Snow's gulch, Iron cañon, Mud Springs, and Tenabo.

NYE COUNTY

Ten mines at Tonopah produced 47,207 tons of ore worth \$896,933 in January. The Extension mill is to be enlarged by another 5 by 16-ft. tube-mill and a Dorr classifier, to increase the daily tonnage to 200 tons. The Jim Butler-West End extralateral right question is being discussed by the Companies' officials.

(Special Correspondence.)—About 27 miles from Luning, in Mineral county, is the Fairplay mining district. This district is attracting considerable attention again. During the past eight years considerable development has been done, and the veins have been proved to a depth of 230 ft. There are large bodies of ore available, assaying about \$25 per ton.

SECTION OF BUNKER HILL & SULLIVAN MINE.

a year. Edison storage batteries operate the locomotives.

The Bullion and Copper Chief companies will drive a joint adit, costing \$34,000, to cut veins in the properties at about 434 ft. from the surface. John H. Nordquist, of Wallace, will superintend the work.

MISSOURI

ST. FRANCIS COUNTY

An appeal from the decision of Justice Cardoza, of the Appellate Court of New York, has been taken by Robert Holmes in his suit to restrain the St. Joseph Lead Co. from borrowing \$2,500,000.

MONTANA

DEER LODGE COUNTY

On February 20 a cave-in occurred at the Southern Cross mine, at Georgetown, burying two men. Rescue crews have been at work. This property is owned by the Anaconda company, ore being shipped to the Washoe plant for treatment.

FERGUS COUNTY

During January, the Barnes-King Development Co. produced 4324 tons of ore, yielding \$44,000 in gold. The profit was \$24,000. On March 4, the annual meeting will be held at Kendall.

SILVERBOW COUNTY

The Butte-Duluth mine has been sold to the American Metals Co. It was reported on by W. H. Weed. Twelve inches of copper glance has been opened 75 ft. below the 2000-ft. level of the Pilot-Butte. The ore assays 1.98% copper and 6 oz. silver per ton. The middle vein, at 1800 ft., is 30 in. wide, containing 7.4% copper and 12 oz. silver per ton. The shaft will be continued to 2600 ft. Water from the mine is only hoisted to the 1300-ft. level, from which it flows through a 700-ft. cross-cut to the Butte & Superior mill. The Anaconda company's suit against the Pilot-Butte, involving the South vein, is to be heard on March 20. The Tuolumne mine produced 184,394 lb. of copper, 9869 oz. silver, and 13 oz. gold in January from 3091 tons of ore. This came from the 800, 1800, 2000, and 2200-ft. levels. A vein was cut on No. 24 level on February 13, but was disappointing. From August 1, 1913, to January 1, 1914, ore shipments totaled

in gold and silver. The ore occurs in andesite and rhyolite. The outlook for this district is promising. By the addition of a cyanide plant to the present milling facilities at the Goldyke, the owners should be able to save the metals and realize good profits. A townsite has been located, called Butler. Fuel and water are found in the immediate vicinity.

The Nevada Chief Mining Co. is operating six claims and has a 15-hp. hoist. An incline shaft has been sunk to a depth of 230 ft. The vein was cross-cut at 150 ft. and assayed about \$20 per ton, and in the lower cross-cut the vein is larger and contains better gold content. The shaft is to be sunk 100 ft. deeper.

The Nevada Chief Extension Co. has several promising claims and is preparing to develop them. The Excelsior Twilight Mining Co. has a good body of ore at a depth of 320 ft. and expects to install a 25-hp. hoist. The Contact Mining Co. has a 150-ft. shaft. On the 100-ft. level the vein is about 2½ ft. wide, assaying \$18 per ton. There are several other groups located and being developed by experienced mining men who have great faith in the district.

Luning, February 10.

STOREY COUNTY

Work is to be resumed in the Mexican and Union mines, which have not been operated of late on account of a difference with the United Comstock Pumping Association. The Pumping Association is keeping the water just below the 2700-ft. level with Starrett pumps. An earthquake of three seconds' duration shook Virginia City district on February 18. There was a fairly heavy shock at 2200 ft. in the Ophir winze, and rocks split off. On the 1000-ft. level of the Consolidated Virginia, 6 by 12-in. timber broke in several places. In the Yellow Jacket the movement was very perceptible, but not much in the Crown Point and Belcher. The Silver Hill Mining Co. has decided to erect a 50-ton mill and cyanide plant in lower Gold cañon. Walter Techow will design, erect, and operate the plant. During 1913 the Crown Point, Belcher, and Yellow Jacket companies produced 32,368 oz. of bullion from 23,943 tons of ore.

NEW MEXICO

GRANT COUNTY

The Lordsburg mining district has been described in *The Lordsburg Leader* of February 12. The S5 mine is producing about 4000 tons of copper ore per month, the output in 1913 being \$650,000. A treatment plant of some kind is contemplated. A branch of the A. & N. M. railway has been surveyed to this and other mines. A deal has been completed whereby the Metropolis mine and a group of claims, near the S5 mine, were taken over by the Amalgamated Lead & Copper Mining Co. from J. C. Waldmann, of San Francisco, California, and associates. A large tonnage of lead-silver ore, and copper ore, has been proved, and a concentrating plant may be erected next fall. Good copper-gold-silver ore has been opened in the Bonny mine, five miles south of Lordsburg. The Miser's Chest, adjoining, has a shaft over 400 ft. deep, the lower levels being under water. In the Atwood, near the S5 and Metropolis, there is a big tonnage of medium-grade ore. It has produced \$300,000. In the Pyramid camp are a number of promising claims. In 1912 the Lordsburg mines produced 55,340 tons of ore yielding gold, \$144,859; silver, 275,251 oz.; copper, 3,155,587 lb.; and lead, 4562 lb., worth \$835,915.

OREGON

BAKER COUNTY

After being shut down for two years, the North Pole mine, near Sumpter, is being developed again. Ralph Clarke is in charge. It is likely that the and the E. & E. mine will be consolidated. Promising discoveries have been made in the New Eldorado district, northwest of Sumpter, in a little known part of the Greenhorn mountains.

UTAH

The radium-bearing ores of this state were discussed on February 20 by L. O. Howard before the Utah Society of Engineers. He said that in Utah the ores of vanadium, uranium, and radium are found in several localities in the eastern districts. These may be described as follows: In Uintah county, near Independence, and extending into Wasatch county; in Grand county, at Moab, Dewey, Richardson, and 16 miles southeast of Thompson's; in Emery county, near the town of Greenriver, and at Table mountain, 45 miles southeast of Greenriver; in San Juan county carnotite has been reported from the vicinity of Monticello, near Dry cañon, and from Copper cañon in the southwest portion of Kane county, minerals similar to those at Richardson are found near Paroah; in Wayne county, in the vicinity of Hanksville and Fruita, and in the Henry mountains, several carnotite claims have been located. At Table mountain, Beebe and Browning started prospecting work on their claims as early as 1903, and in the Greenriver field, location notices which were put up about the same time have been found. The ore occurs in a sedimentary formation. The beds have suffered considerable erosion, but when this has not been too deep a thin bed of quartzite lies on the highest portions. Beneath this is a medium coarse to fine conglomerate. Beneath the conglomerate lies a coarse-grained white sandstone, underlain by a thin seam of green shale. The ore is found principally as an impregnation of the sandstone and lies in any part of the same near the surface, sometimes immediately underneath the conglomerate, at others on top of the shale. The conglomerate is sometimes the source of valuable ore and occasionally the quartzite shows a slight mineralization. The principal mineral is the canary yellow carnotite, whose color is often obscured, and a variety of earthy minerals usually accompany it. The various minerals present a great variety of colors: black, all shades of green, yellow, and blood red. The black is sometimes glossy like coal, sometimes talcy, and sometimes dull earthy. These are usually the best grades of ore. It occurs in pockets from a few inches up to five or six feet thick.

JUAB COUNTY

The winze below the 1000-ft. level of the Tintic Standard is down 70 ft., and a foot of high-grade galena is being sunk on. A carload of gold-bearing ore is being shipped from the Victoria. It will average \$75 per ton.

SALT LAKE COUNTY

The Utah Copper Co. has ordered four 2500-kva., water-cooled transformers from the General Electric Company.

WASHINGTON

FERRY COUNTY

The Orion Mining Co., at Covada, has opened rich silver ore, 1400 ft. in the adit being driven. Good ore is showing in the Keystone, and lead ore in the Big Joker.

STEVENS COUNTY

Charles F. Soderling, of Spokane, and his associates have taken a bond on the Mayflower group of three claims in the Chewelah district, for \$20,000. The first payment is to be made in 12 months. The property has been operated under the name of the Big Bend Mining Co. by Dickey, Bramley, and Hyde. The ore has been traced on the surface of this group for 4500 ft. An 8 ft. vein containing copper and silver has been cut by a short adit. During 1913 the United Copper Mining Co. produced 14,938 tons of ore and concentrate, yielding 84,762 lb. of copper and 134,437 oz. of silver. Mining cost \$6.19 per ton, and freight and treatment to the Grand Forks and Frodo smelters were \$1.50 and \$5 per ton, respectively. Developments at 400, 500, and 600 ft. are in progress. The net earnings were \$149,841. Conrad Wolfe is president of the company.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—S. J. Eubank and D. F. Jones will diamond-drill their San Diego group of six claims, situated six miles from the head of Alice arm in the Cassiar district. There has been considerable development done on this property, and the showing is good. A horse trail has been completed from the head of the arm to the property, and a drill outfit with a capacity of 400 ft. depth has been ordered and will arrive about May 1.

Anyox, February 16.

The new Hidden Creek smelter of the Granby company is practically completed, but weather conditions have seriously interfered with the blowing in of the furnaces. It was expected that it would have been started on February 10, but it may take several weeks yet, as there is not sufficient water in the reservoir for the hydro-electric plant. During the first two weeks of February the Grand Forks smelter treated 47,213 tons of ore and shipped 782,000 lb. of blister copper.

ONTARIO

Bullion shipments from three Cobalt mines during the past week totaled 258,359 oz., and 916,465 oz. for the year to date.

On the 460-ft. level of the Beaver Consolidated the granite intrudes into the Keewatin, and from 4 to 6 in. of ore has been opened for 15 ft. in the granite, containing about 3000 oz. silver per ton. This development in granite was not expected and has caused considerable discussion. During 1913 the Trethewey mine produced 619,427 oz. silver worth

GEOLOGICAL SECTION OF COBALT.

\$365,611. Freight, sampling, and smelter charges were \$32,000. Dividends amounted to \$150,000, and the surplus for the current year is \$146,148. Ore reserves contain 585,970 oz. silver.

The Dome, at Porcupine, treated 13,900 tons of ore in January, yielding \$111,500. The mill worked 93% of the possible time.

The following shipments were made in January: Casey Cobalt, at New Liskeard, 59 tons silver ore; gold ore from Haileybury, 35 tons; copper ore from the Dane mine, 66 tons; silver ore from Elk Lake, 32 tons; and nickel ore from the Alexo mine, Porquis junction, 744 tons.

COLOMBIA

The Pato dredge recovered gold worth \$10,600 from 14,500 cu. yd. during the week ended January 27.

MEXICO

SONORA

The Lucky Tiger-Combination Gold Mining Co., operating at El Tigre, reports that during January the mill crushed 6115 tons of ore, and the cyanide plant treated 7754 tons of tailing. The yield from shipping ore, concentrate, and bullion was \$135,749. The estimated profit was \$60,974. On February 1 all of the outstanding bonds of the Company were retired.

Personal

CHARLES J. GARVIN is in New York.

THOMAS B. STEARNS is in New York.

HOMER L. CARR has gone to Honduras.

L. D. MILLS has returned from South Africa.

C. W. GOODALE is expected in New York soon.

CHARLES PETER has returned to Salt Lake City.

H. DEWITT SMITH has gone to Kennicott, Alaska.

MORTON WEBBER, of New York, is at the St. Francis hotel.

T. J. ANDERSON sailed from New York for Panama on February 18.

CHARLES BUTTERS has returned from Salvador and is in New York City.

JACK HOFFMANN has gone to Tcherdin, in the Ural region, with CHARLES JANIN.

N. B. KNOX sailed on the *Kronprinzessin Cecellie*, February 21, returning to London.

F. C. MOORE, manager at the Star of the Congo mine, is visiting the United States.

JAMES DOUGLAS, L. D. RICKETTS, and WILLIAM THORNTON have been inspecting the Greene Cananea mines.

ERNEST RUTHERFORD, Langworthy professor of physics in the University of Manchester, has been made a knight, taking the title of K. B.

F. J. JANEY, J. M. HYDE, S. GREGORY, and A. M. HIGGINS were among those attending the argument of the case of Minerals Separation, Ltd., versus James Hyde on appeal at San Francisco last week.

J. M. HYDE has returned from a trip through Europe investigating the newer metallurgical processes and will be the American representative of Murex Magnetic Co., Ltd., at San Francisco.

ELWOOD MEAD, chairman of the Victorian Water Commission, left Sydney on February 7 on the *Sonoma* for San Francisco, for the purpose of securing, if possible, a cancellation of his agreement to undertake the duties of professor of Rural Institutions at the University of California, in order that he may be able to complete his work in Victoria. In his absence W. CATTANACH will act as chairman of the commission.

Schools and Societies

THE ENGINEERS' CLUB of Philadelphia met on February 21, when Arthur W. Goodspeed lectured on 'Radio-activity, with special reference to radium.'

The Civil Engineering Department of the UNIVERSITY OF ILLINOIS held a special short course in Highway Engineering during the last two weeks of January. The number registered was 191 students, of whom 63 were county superintendents of highways.

THE AMERICAN ELECTROCHEMICAL SOCIETY will hold its annual meeting and election on April 16. The spring meeting, to be held on April 16, 17, and 18 at New York, will be an interesting one. Questions to be discussed are, 'Power for Electrochemical Purposes,' and 'Hydro-electrometallurgical Processes.'

THE CLEVELAND ENGINEERING SOCIETY held its regular meeting, on February 10, at Cleveland, Ohio, when a paper on gas power was read by R. H. Fernald of the Bureau of Mines. A semi-monthly meeting will be held on February 24, when a paper on 'Acoustics and Engineering' will be read by Dayton C. Miller.

The Metal Markets

LOCAL METAL PRICES

San Francisco, February 26.

| | |
|--|------------|
| Antimony | 9 — 9½c |
| Electrolytic copper | 15½—15¾c |

| Quicksilver (flask) | \$39.00 |
| Tin | 42½—44 c |
| Spelter | 6½—6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c per pound. | |

EASTERN METAL MARKET.

(By wire from New York.)

NEW YORK, February 26.—Copper still shows a downward tendency, and little business is being transacted, buyers holding off. Lead is firm at 4c. per pound, and spelter is quiet at 5.20c., a slight reduction on last week's quotations. The Chino, Nevada, Ray, and Utah copper companies have declared their regular quarterly dividends, payable March 31. Trading on the Stock Exchange today covered 316,100 shares, and bonds worth \$2,678,500. Stocks generally were lower than last week. In London copper closed firm at £64 6s.3d. for spot, and £64 18s.9d. for futures, both small increases. Lead is 119 2s.6d., up 2s., and spelter is 121 10s., remaining unchanged.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | Average week ending. |
|-------------------|----------------------|
| Feb. 19..... | 57.50 |
| " 20..... | 57.50 |
| " 21..... | 57.50 |
| " 22 Sunday..... | 57.50 |
| " 23 Holiday..... | 57.50 |
| " 24..... | 57.62 |
| " 25..... | 57.50 |

Monthly averages.

| 1913. | 1914. | 1913. | 1914. |
|-----------|-------|-------|-------|
| Jan. | 63.91 | 57.58 | 58.70 |
| Feb. | 61.25 | 57.58 | 59.32 |
| Mch. | 57.87 | 57.58 | 60.53 |

| May | 60.21 | 57.58 | 58.76 |
| June | 59.93 | 57.58 | 57.73 |

The tendency of London prices has been good, according to Samuel Montagu & Co. on February 5. The highest quotations of the week were on the 2nd, when cast silver was fixed at 26 11/16d. (54.4c.), and forward silver 1/4d. (0.5c.) lower. During the rest of the week a 1/4d. (0.5c.) difference obtained. Business has been of an all-round character, but Indian buying orders have been only on a small scale. During the month of January, the market was not active. This is traceable, inter alia, to two causes, namely, the usual arrest of fresh business in China at the period of the Chinese New Year, and to the digestive process necessary in regard to the speculative stock once held by the Indian Specie Bank. Prices have been maintained within fairly narrow limits, 5/16d. (0.62c.) in the case of both cash delivery and two months' delivery. A certain proportion of the bear accounts, open at the end of last year, has been closed; but the most substantial part is still uncovered, or has been renewed. The Indian bazaars have kept a bearish sentiment throughout, and have only dealt from hand to mouth.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

| June | 14.71 | 14.21 | 14.25 |

Stocks of copper in England and Europe at the end of January were as follows, according to Henry R. Merton & Co.: English standard copper in Liverpool, Swansea, and Port Talbot, 7925 tons; other standard at Liverpool and Swansea, 1261 tons; and standard at London, Newcastle, and Birmingham, 1113 tons; furnace material at Liverpool and Swansea, 130

tons; fine copper in Havre, France, 1712 tons; Rotterdam, 3650 tons; Hamburg, 3842 tons; and Bremen, 1621 tons; a total of 21,244 tons. Fine copper afloat from Chile and Australia was 4700 tons. Stocks at other European ports were estimated at 750 tons.

Everybody seems to be in more or less of a fog about the copper market, though there is really nothing very mystifying about it. Everyone has known that foreign shipments have been large, and not a few doubt whether they really reflect the present state of consumption in Europe. Domestic deliveries in January showed an encouraging increase over December, and certainly do not lag behind the revival in domestic industry for which everyone is hoping, for there is no denying that it has not yet given much clear evidence of its sure arrival. Now that the Rio Tinto strike is finally settled and the winter weather, which cuts down the output of some mines, will soon end, production will probably increase, and it is good that consumption gives evidence of increasing as well.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

Monthly averages.

| 1913. | 1914. | 1913. | 1914. |
|-----------|-------|-------|-------|
| Jan. | 50.45 | 37.85 | 40.70 |
| Feb. | 49.97 | 37.85 | 41.75 |

| May | 49.10 | 37.85 | 39.77 |
| June | 45.10 | 37.85 | 37.57 |

At the end of January, speculative interest in the tin market in London assumed large proportions, according to Henry R. Merton & Co. Bears have been frightened by the rapid advance into covering their commitments, while a good deal of buying for a further rise took place. There has been heavy buying on the part of American consumers. Transactions during the last week were 3500 tons. English ingot tin was 71s. per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

SULPHUR PRODUCTION of the Sicilian Sulphur Combine, during the year ended July 31, 1913, was 351,752 metric tons. This is a decrease of 15,489 tons compared with the previous year. Seven mines were shut down, and 16 in 1912. Stocks on hand were 354,169 against 444,381 tons. Total sales amounted to 497,246 against 603,255 tons. Exports declined from 447,638 to 434,473 tons. Those to the United States were only 1792 tons. Competition with the Union Sulphur Co., which will distribute American sulphur in Europe from headquarters at Rotterdam, has been keen. The general apprehensions that foreign competition is liable to seriously damage the Sicilian sulphur industry should be dismissed for the following reasons, according to the annual review of the Sicilian Sulphur Combine: (1) That the Freeport Sulphur Co., which began operations in 1911 in exploiting the sulphur deposits in Texas, failed to obtain the results it had anticipated, due chiefly to considerable technical difficulties; (2) that Japan has not increased its exports, which is evidenced by the increasing demand for sulphur from the Pacific markets; (3) that the rumors of large sulphur deposits on White Island, New Zealand, have not been confirmed; (4) that the sulphur deposits in Spain are completely exhausted; and (5) that no definite information has been received announcing the alleged increase of sulphur production in Mexico.

FINAL FIGURES of the gold output of the Rand are now available, and show the following results for 1913, compared with the previous year:

| | 1912. | 1913. |
|------------------------|-------------|-------------|
| Gold, fine ounces..... | 9,124,299 | 8,794,824 |
| Value..... | £38,757,560 | £37,358,040 |
| Dividends..... | £8,277,862 | 8,500,000 |

Total dividends since 1886 amount to £100,049,158, and gold output since 1884, £401,242,675. At the end of December 1913 there were 150,012 native laborers at the gold mines, compared with 191,316 at the end of 1912.

PUBLIC LANDS in the United States, restored to entry in December, covered an area of 1,678,000 acres. The area standing as withdrawn from entry at the end of last year was 66,270,000 acres. The total area of lands which have been classified in western states up to the end of December aggregates nearly 295,700,000 acres.

PRICES of radium-bearing ores varied greatly in 1913, and returns to the U. S. Geological Survey showed that the price per pound for contained uranium oxide ranged from \$1 for ores carrying 0.6% uranium oxide to \$4.60 for one lot carrying 3.15% uranium oxide and 4.82% vanadium oxide.

RADIUM BROMIDE worth \$1,055,000 was the equivalent content of the uranium ores mined in the United States in 1913, according to the U. S. Geological Survey. The ore exported to Europe was 942, and that retained in this country was 1198 tons.

THE United States Steel Corporation, under its compensation plan, paid over \$2,200,000 in 1913 for injuries to its employees.

THE UNITED MINER WORKERS OF AMERICA has a membership of 415,142 men.

Company Reports

THE JUMBO GOLD MINING COMPANY, LTD.

This Company owns 20 claims in the Mazoe valley, about 30 miles north of Salisbury, Rhodesia. The report for the year ended June 30, 1913, gives the ore crushed as 37,180 tons, yielding £57,804. Operating costs were £57,830, divided as follows: mining, \$2.49; milling, \$1.37; sand treatment, 56c.; slime treatment, 32c.; and general charges, 56c. per short ton. The profit was £16,685.

RAY CONSOLIDATED COPPER COMPANY

The report of this Company, operating in Arizona, covers the last quarter of 1913. Underground work amounted to 21,042 ft., making 376,972 ft. to date. The orebodies tributary to No. 1, 2, and 3 shafts produced 62, 33, and 5%, respectively, of the ore mined. Results were as follows:

| | |
|---|------------|
| Ore milled, tons | 665,024 |
| Average copper content, per cent | 1.7152 |
| Copper output, pounds | 15,004,727 |
| Recovery, per cent | 65.773 |
| Cost of mining, including coarse crushing, cents per ton | 70.768 |
| Cost of milling, including improvements, cents per ton | 57.739 |
| Cost of copper produced, cents per pound..... | 9.9801 |
| Mine development extinguishment, cents per ton... | 12.5 |
| Profits, including dividends of Ray & Gila Valley Railroad, etc. | \$ 744,018 |
| Dividend | 543,951 |
| Dividends for 1913 | 1,631,504 |

The average price received for copper during the quarter was 14.831c. per pound. At present the mine is producing almost 8000 tons of ore per day. Practically all construction work is complete.

CHAMPION REEF GOLD MINING COMPANY OF INDIA, LIMITED

This Company operates one of the great gold mines of the world at Kolar, in the state of Mysore, India. The report for the year ended September 30, 1913, shows that 140 stamps crushed 220,511 tons of quartz, yielding 103,797 oz. gold, while 339,587 tons of tailing and slime yielded 29,122 oz. gold, the whole product being worth £510,737. Since 1892, there has been crushed 3,179,185 tons of ore yielding gold worth £10,620,037. Dividends in 1912-13 were £130,000, making a total of £4,018,966. Royalty paid to the Mysore government in 1913 amounted to £28,555. Material and stores at the end of the fiscal year were valued at £50,517; cash in London and India, £68,619; and reserve fund, £45,000. Total costs were \$6.37 per ton milled. The expenditure on shafts, buildings, and equipment was £64,917.

The report of the superintendent, H. J. Gifford, contains the following notes: Total work done covered 17,755 ft. Development south of Garland's shaft has been mostly unproductive owing to the intrusion of a cross-course. At No. 40 level this had not dipped north so rapidly, consequently the north drift on that level entered ore sooner than expected, and ore of good width and value has been opened. Ore will probably be cut again at lower levels south of the cross-course. Garland's shaft is 4289 ft. deep at an angle of 70°. Glen shaft was sunk 240 ft., or 41 ft. below No. 43 level. The country between these two shafts showed favorable results, and a continuous shoot of good width and value has been opened in each of the five deepest levels. Development south of Carmichael's shaft has been variable, but the ore is of good grade. The shoot is 1026 ft. long on No. 44 level. Airblasts have been less frequent, but have caused loss of

life among the native miners. In order to minimize risks, work has been temporarily suspended between No. 19 and 25 levels. Glen and Ribblesdale's shafts have been damaged by these shocks. The Circular shaft is down 3861 ft., and has been bricked for that distance. Ore reserves in the mine total 404,125 tons, not including 46,302 tons to be left to support certain areas where air-blasts are troublesome. The Champion Reef lode is not a wide one, being from one to several feet thick.

Details of the mill work will be published in another part of this journal. There were 6716 employees during the last month of the fiscal year, of whom only 143 were Europeans and 91 Eurasians. The report is accompanied by complete plans of the mine and other details of its operation. John Taylor & Sons, of London, are general managers of the property.

In January 1914 the mill crushed 18,070 tons of ore and treated 28,632 tons of sand and slime, yielding gold worth \$212,000.

BRUNSWICK CONSOLIDATED GOLD MINING COMPANY

This Company's mine and mill is at Grass Valley, Nevada county, California, and the report deals with the work done during 1913. The manager, R. Chester Turner, states that 1219 tons of low-grade ore was mined by lessees from the old mill ore-shoot, the balance of the 15,334 tons sent to the mill coming from No. 4 shoot, lessees taking out 2430 and the Company 11,985 tons. Development covered a total of 2076 ft. From 15 to 22 lessees have been working in the mine, but as No. 4 shoot is well developed, the tendency is to limit the quantity of tribute ore. This shoot maintains its length of from 400 to 500 ft. The vein dips south, and the upper or northern edge bends or curls over, forming what appears to be a saddle reef, with the vein dipping north and south from the apex of the saddle. Probably on account of this bending and flattening of the upper portion, the 600-ft. level cross-cut has not cut the vein. This will most likely be found considerably west of the crosscut. The superintendent, C. H. Mallen, reports that No. 4 shoot continues to furnish the 20-stamp mill with a good grade of milling ore. From the present workings to the surface is about 900 ft. on the pitch of the vein. The vein is strong, with good walls and every indication of considerable extent. Little change has occurred since stoping commenced above the 1250-ft. level. No doubt is felt that this is one of the big ore-shoots of Grass Valley. It was found on the 1250-ft. level and about 2000 ft. east from the old incline shaft, and working toward the surface, as has been necessary, prevents the making of reliable estimates of tonnage. The new three-compartment shaft is completed to the 1250-ft. station. The rock is hard, but future repair work will be small. With the Company's facilities for handling ore and material for the mine through this shaft, it will be able to work as many stamps as the mine requires, with much less expense and greater speed. Sinking has been started under the floor of the 1250-ft. level, and the vein may be cut in about 200 ft., depending on its pitch. Mr. Turner also reported that the connection between the new vertical shaft and the vertical raise from the 1250-ft. level, in February 1913, was well done, the difficult surveys being made by E. C. Uren, of Nevada City. Ore reserves consist of about 15,000 tons, some varying from \$10 to \$25 per ton. Mining costs were \$5.11 per ton. Financial results were as follows:

| | |
|---|-----------|
| Ore treated, tons | 15,334 |
| Gold and silver recovered | \$208,359 |
| Output since 1897 | 866,705 |
| Revenue in 1913, including bullion, 1912 balance and sundries | 229,583 |
| Expenditure | 152,888 |
| Dividend No. 2 | 23,717 |
| Balance | 43,978 |

A New Rock-Drill Operated by Gasoline Engine

The 'Temple-Ingersoll Gasoline-Air' rock-drill has been placed on the American market during the past month by the Ingersoll-Rand Co. At present it is made in only one size, and the equipment employs the same type of drill and pulsator as are used with the 'Temple-Ingersoll Electric-Air' drilling unit. The electrical equipment of the latter type, however, is replaced by a 6-hp. single-cylinder gasoline engine. The gasoline motor, supply tank, and pulsator are all mounted on a four-wheeled truck to permit easy transportation. It is believed that the 'Temple-Ingersoll Gasoline-Air' drill possesses the advantages peculiar to the 'Electric-Air' drill, and also prove particularly suitable for use in situations where electric power cannot be economically or advantageously applied. The following description is furnished by the manufacturers:

The gasoline engine is of the jump spark type, the ignition spark being obtained from dry cells. The circulating water is obtained from any convenient receptacle placed near the equipment. A gasoline supply tank, of $1\frac{1}{4}$ gal. capacity, surmounts the engine. The fuel consumption of the engine, running under load, is about two quarts of gasoline per hour, so that the average daily fuel consumption would be approximately three or four gallons.

TEMPLE-INGERSOLL GASOLINE-AIR DRILL.

The drill proper of the 'Gasoline-Air' unit is driven by pulsations of compressed air created by a pulsator actuated by the gasoline motor. Gearing transmits the power from motor to pulsator. The air is never exhausted, but is simply used over and over again, playing back and forth in a closed circuit. The pulsator is a simple machine, employing no water jackets.

The drill is the simplest type possible, a cylinder containing a moving piston and rotation device, with no valves, chest, buffers, springs, or side rods. The weight of the drill unit is about the same as or even less than that of the corresponding air drill. The ordinary air or steam-driven rock-drill takes a full cylinder of air or steam at full pressure each stroke, and discharges it to atmosphere at practically full pressure. No advantage, therefore, is taken of the expansive properties of the air or steam, and as a result an amount of power is wasted without doing useful work. The 'Gasoline-Air' drill operates with a closed system filled with air under a low pressure, which is simply an agent for transmitting the effort of the pulsator piston to the drill piston. The air in the system has been aptly referred to as pneumatic 'spring.' That the saving in power is great is proved by the fact that, under ordinary conditions, the drill proper of the 'Gasoline-Air' unit uses about one-fourth the horse-power required for the usual air or steam drill, of the same work capacity. It has a stroke equal to or even greater than that of the air-

driven rock-drill of corresponding capacity. The length of stroke is varied simply by cranking forward in the shell, and both stroke and force of blow may be adjusted by the same means for fast drilling under any circumstances. If a hole should 'mud up,' the machine can be backed out without injury while running. The cushioning is such that the piston, in running, does not normally strike either front or back head. The system of lubrication of the pulsator is automatic and complete, the 'splash' method being employed. While most of the oil drains back to the crank chamber, a portion is atomized and carried through with the air into the drill.

The drill cylinder diameter is $4\frac{3}{4}$ in., and the stroke is 7 in. The drill will accommodate octagon steels of from 1 to $1\frac{1}{4}$ -in. diameter, drilling holes of from $1\frac{1}{4}$ to 2-in. diameter. The drill feed is 24 in. The approximate strokes per minute are 440. The machine is designed to drill holes up to about 12 ft. in depth. Its field covers quarrying and contracting operations, particularly those in isolated locations where the high cost of coal forms a serious handicap to operations. Its advantages for winter operations in quarries will also be apparent to those who have experienced trouble from the freezing of ordinary drills.

Catalogues Received

THE NATIONAL TUBE Co. has prepared a bulletin, No. 19, which includes a complete list of National products, arranged conveniently for quick reference.

THE PLATT IRON WORKS Co. is now distributing a special bulletin, No. 741, descriptive of the 'Smith-Vaile' line of pumps which are now made in wide variety of style and size to meet all conditions of drive and service. Particular attention is invited to the heavy standard frames, and the heavy pressures used with both the single and double acting pumps.

THE DORR CYANIDE MACHINERY Co. catalogue for 1914, now available, begins appropriately enough with a picture of the Lundberg, Dorr & Wilson mill at Terry in which Mr. Dorr's early experiments were conducted. Following this are descriptions of Dorr classifiers, continuous thickeners, agitators, and the counter-current system of decantation with lists of the leading mines in which each is used.

THE PELTON WATER WHEEL Co. catalogue for 1914 includes not only excellent pictures and descriptions of the various types of wheels, valves, and other machinery built by this pioneer Pacific Coast concern, but numerous tables and other data of wide use to engineers. Among other features may be mentioned tables of weir measurements, tangential water-wheel tables, and safe working heads and weights of riveted steel pipes.

C. F. BRAUN & Co., Pacific sales manager for the Alberger Pump & Condenser Co. is sending out bulletin 100, containing a complete description of 'Hammond' water meters, with the following special bulletins: No. 1, 'Blackburn-Smith' feed water filter and grease extractor; No. 2, 'American' water softener; No. 3, 'American' pressure filters; No. 4, 'Wainwright' feed water heaters for marine service; No. 5, 'Centrifugal Pumps for Irrigation' the latter being a reprint of an excellent article published in *Western Engineering*.

THE MARION STEAM SHOVEL Co. has built some of the largest shovels and dredges in use but it also builds small shovels and has recently issued an attractive booklet of particularly convenient size, $4\frac{1}{2}$ by $8\frac{3}{4}$ in. describing the Marion revolving shovel and illustrating the great variety of work now being economically accomplished with it. The catalogue is especially concise, and contains a good index as well as a table of working dimensions that furnishes a quick and easy method of obtaining necessary specification data.

EDITORIAL

ACKNOWLEDGMENT should have been made to the *Weekly Trinity Journal* for the description of the Globe mine and mill printed in our issue of February 14. Owing to a misunderstanding of letters, this was not done at the time the article was printed.

OUR congratulations are extended to the Institution of Mining and Metallurgy which is now conveniently housed in its own building, No. 1 West street, Finsbury Circus, London. We trust that the new building will prove a home rather than a new house. The rooms in Salisbury House, 722 to 724 inclusive, made vacant by the removal of the Institution, are now occupied by *The Mining Magazine*, so we may fairly claim to be following in the footsteps of the Institution.

ANONYMOUS contributions can not be published for the simple reason that publication of any matter involves legal responsibility and a rule that is once broken is almost certain to lead through growing exceptions to trouble. Where there is any good reason, as there may well be, why the name of the author should not be used, an editor will gladly preserve his incognito; but material that comes to the editor with no name, a fanciful name, or an unknown name, must be sent to the waste basket even though it be often with regret. We have now a very clever letter regarding 'ore' that we are unable to use for these reasons.

NEW theories of ore genesis are constantly "tossed off" by those who develop them "while smoking a quiet pipe," but who seemingly are content to leave to others the critical testing of such hypotheses. Not long ago we saw a letter written to one of the larger exploration companies from an amateur scientist who had decided that in all gold-bearing districts the gold must eventually gravitate to the pools below waterfalls, and who thereupon submitted the idea as a final solution to the problem of gold finding. With rare generosity he did not ask for any amount down, but a reasonable percentage of what it may yield," in Canada and the United States. He also reserved all rights in other countries, such as Australia, New Zealand, and South Africa. We consider this infringement. Long ago we came to the conclusion that placer gold was found in placers and, not to be outdone in generosity, we offer the theory to anyone who cares

for it and shall only ask a modest royalty on any gold that may be found as a result.

JAVA is to hold a General Colonial Exposition, August to November, inclusive, this year. Elaborate preparations are being made at Semarang. A park of 70 acres has been set aside for gardens and buildings. The Dutch have made a notable success of their colonial enterprises, and to Americans, whose minds are in two ways regarding colonies, the exposition will be especially interesting. It will also afford a good opportunity to cultivate foreign trade in the Far East. Those who wish detailed information may obtain it from Mr. T. Greidanus, 136 Water street, New York City.

DESULPHURIZING ores without roasting is accomplished at the 'low-grade' mill of the Nipissing Mines Company by an interesting process described for our readers by Mr. J. J. Denny, September 27 last. We understood at the time that the process, which involves the use of metallic aluminum to break down the sulphides, was neither patented nor patentable. We are now informed that application for patents in the United States and the principal foreign countries had been made in behalf of the Butters-Johnston Engineering Syndicate, even before the publication of Mr. Denny's article. Intending users of the process should therefore make sure of their ground before adopting it.

MUCH as we admire our brilliant contemporary, *Metallurgical and Chemical Engineering*, we cannot accompany it on its forays into the realms of natural history. Recently it sought to illustrate the present situation at Niagara Falls by means of a fable in which a beaver and an eagle enter into an agreement to divide the fish they catch, an arrangement which worked admirably until a tiger appeared and demanded a share of the spoil. Possibly the metamorphoses effected by the metropolitan fur dealers, who without difficulty transmute a raccoon into a Hudson seal, have so bewildered the New York editor that he confuses a beaver with an otter and an eagle with an osprey, but where does the tiger come in? Fortunately Mr. Theodore Roosevelt is still in South America and the life of the nature-faking chemical engineer is therefore not in immediate danger, but we advise him to accept an engagement which will take him to the Lena goldfields, or some equally inaccessible place, at the earliest possible moment.

WORKMEN'S compensation acts are beginning to be productive of interesting judicial rulings. The courts have held that rattlesnakes indigenous to the country constitute an industrial hazard, and a workman bitten is entitled to compensation. Whether this should be in liquid form, the *New York Sun*, which reports the ruling, does not state. Similarly, a boy who shot a workman in the eye with an airgun was considered an industrial hazard, but a brutal boss who whipped his workman was not, nor was compen-

sation allowed to the relatives of a workman whose enemy waylaid him and shot him while at work. This reminds us of the young woman who brought suit for damages against a railroad company in the West. It appeared that a brakeman, smitten by her charms, had thrown her a note tied to a torpedo. The maiden thrust them both into the kitchen stove and was severely injured by the resulting explosion. The court, after careful consideration, ruled that the brakeman's act was not in the performance of his normal duties, and the suit was dismissed.

STATISTICS are an infallible means of conveying misconceptions, especially when hastily considered. The carefully compiled and accurate statistics of the Copper Producers' Association show the stocks of copper on hand at the refineries on the first day of each month. Probably many people regard this as an index of what may be called the liquid stock of copper available in this country. We recommend to all such, consideration of the fact that the Association's report of marketable copper on January 1 was 91,000,000 pounds, while the quarterly reports of the Utah, Chino, Ray Consolidated, and Nevada Consolidated companies showed that on the same date they held a total of 109,000,000 pounds of copper. The difference is, of course, due to the fact that two different things are represented, the former being refined copper, the latter blister as well as refined metal. Just as the long large pipes of a waterworks system have considerable storage capacity, so the yards of smelters, freight cars, and warehouses serve to hold a large stock of copper, which is, in part at least, effective as a reserve stock, but which does not figure in trade statistics.

IT is not uncommon experience that gold mines turn into copper mines in depth, the Mount Morgan being the most notable example, and it is natural, therefore, to find a gold mining company turning its attention toward copper. These reflections are prompted by the announcement that the Exploration Company, Ltd., has invested \$450,000 in the bonds of the Chile Copper Company, the big new mine which the Guggenheim Exploration Company has developed at Chuquibambilla, Chile. The chairman of the Exploration Company, in his speech at the general meeting of the Company in London, on February 17, stated his belief that the estimated cost of 6 cents per pound of copper laid down in Europe is on the safe side, and estimated that with a plant treating 10,000 tons per day of the 2 per cent ore, 120,000,000 pounds of copper per year could be produced at a profit of about \$10,000,000 yearly. The Exploration Company had previously acquired investments in copper mining companies in this country, and its present policy is to increase its copper mining interests. The advent of so well established a company into a field where many reputable large organizations are already engaged is cause for mutual felicitation. Meanwhile those who are inclined to read between the lines are likely to consider this

action as evidence of a belief by well informed persons that a larger field for expansion of operations exists in copper mining than in gold mining; a belief with which we agree.

PUBLICATION of the third edition of 'Lindley on Mines' is an event. The new edition, which was given to the public February 27, shows extensive revision and rewriting. The three bulky volumes are notable not only for the new matter included, but for the incisive presentation of a vast amount of material, here reduced to system and order. They also make fascinating reading even for the layman, as Mr. Curtis H. Lindley is no mere 'dry as dust' lawyer. He knows men, history, and times as well as law, and this, as well as much diligence, has contributed to making his book a notable one. Such a work **can** not be reviewed in the conventional sense, but we hope at another time to present an appreciation of it which shall be adequate in spirit if not in subject-matter.

Vocational Training and Miners

Discussing educational matters a few weeks ago, we mentioned the contradictory expressions of opinion by Mr. Nicholas Murray Butler, president of Columbia University, and Mr. T. W. Robinson, as regards vocational training. Mr. Butler sees in it a dangerous agency working toward a stratified social order and the extinction of individual initiative. On the other hand, Mr. Robinson believes that it results in greater industrial efficiency and increased truth, morality, and attention to civic duty. This conflict of opinion illustrates how little has really been determined regarding the best way to correlate education with life. In the old days of household industries vocational training was obtained at home. The school could well afford to devote itself exclusively to stimulation of the intellectual life of the pupils, because the other work was done. As the factories grew up the school held its own, but the specialization of industry cut off the factory employee from that broad training which his father had acquired while learning how to earn his living. The very absence of such stimulus led him to value it the more, and America has come to be known for the lavish expenditure made upon schools. Yet no reflecting person feels sure that the public school system is doing for future citizens what may rightly and properly be expected.

We have received from Mr. G. McM. Ross a thoughtful letter discussing this fact and calling attention to the Virginia City School of Mines, an outgrowth of the 'Comstock Class of Mining and Metallurgy,' of which Mr. Ross was the originator. We have had occasion previously to commend the work of this school and to express the wish that others of its type might be founded. It is a school for working miners and is designed to afford to the men in the mines an opportunity to learn about the things that concern them most in their daily life. It is akin to the continuation schools

of the German system, though its pupils do not necessarily come to it with the same thorough preparation. In Illinois, with the hearty coöperation of miners and operators, the State University is taking up the work of miners' institutes, and in various parts of the country there is a feeling of distinct need of a closer relation between the schools and the lives of miners as well as of mechanics in general. It is not that more colleges of mines are wanted, for there are more than enough now. More engineers are trained than can be absorbed by the industry, but the man in the ranks does not get the attention that he deserves. It is not too much to say that private correspondence schools afford now the most effective means that we have for meeting the needs of the miners, though the larger manufacturing companies make provision for helping their men to learn. It is well known that the great majority of the students in the public schools never get beyond the grades. They go into the mines, mills, and factories with only the elements of an education, and they face there a wholly new discipline and a wholly new set of ideals. In an effort to hold the boys and at the same time to bring shop and school together, the University of Cincinnati has arranged with owners of large plants for a coöperative course. One set of scholars works in the shops in the morning and in the schools in the afternoon, and exchanges places with another set at midday. In this way there is no interruption of routine, and yet school and work are taught at the same time. Mr. Ross proposes a similar plan for all lines of work, but would extend it to the lower grades as well as the high school and college. This is in accord with sound pedagogy, since Madam Montessori has shown that such training should be begun at the earliest possible moment. Mr. Ross points out that in each community it would be possible thus to give at the same time both vocational training and a general education to each child. The suggestion is worthy of the most careful consideration of professional educators. To our way of thinking, it is the absence of vocational training that endangers the present free rise of a workman from the ranks to leadership. There is nothing which would seem likely to make a man more 'class conscious' in the disagreeable sense of the term, than the knowledge that he had, somehow, been cheated out of the learning and broad training that would permit him to rise from the dead level. Some years ago the farmers woke up to the fact that the schools and colleges were not doing for them what they had a right to expect. The result was the system of agricultural colleges, short courses, farmers' institutes, experimental farms, and the whole system of agricultural education which is the newest and in many ways the most interesting phase of the American educational system. The first attempts were crude, and the system is far from perfect even yet, but it has abundantly justified itself in returns both of money and human character. If Mr. Ross' suggestion as a whole is too radical for us now, why, at least, cannot the miners have what the farmers already have?

THIRD BEACH LINE OF WINTER DUMPS.

Drift Mining in the Frozen Gravel Deposits of Cape Nome

By ARTHUR GIBSON

The following data were collected from and based on actual mining operations at some of the best and most successful mines on Seward Peninsula, Alaska. The numbers 1 to 5, inclusive, refer to the columns and properties in the accompanying tables.

No. 1. All work was performed during the winter, except sluicing and extracting the gold from the pay-dirt, which latter process was performed in the spring.

No. 2 and 3. All work was performed during the summer.

No. 4 and 5. Preparatory work was performed during the early spring, and all stoping, actual mining and sluicing was performed during the summer.

The preparatory work consists in sinking shafts, driving one or more main drifts through the pay-dirt from the bottom of the shaft, and cross-drifts from the main drifts, together with all necessary timbering and lagging. A sump is provided to collect the water from condensed steam and melted ice. All necessary mining machinery must be installed and the necessary buildings for the workmen erected during the early spring.

All thawing of the frozen auriferous deposits was performed during the night shift. All excavation or actual mining was performed during the day shift. The waste or overburden necessary to be removed in order to provide head-room for the workmen was thrown back or behind the workmen as the stope progressed toward the shaft; the pay-dirt was shoveled into dump-cars, holding from 8 to 13½ cu. ft., which run on light steel rails and are handled by manual labor. The pay-dirt is dumped into self-dumping buckets at the bottom of the shaft and hoisted to the surface by means of steam-driven hoists and steel

cables, and deposited or emptied during the winter season in a dump, at property No. 1; and during the summer season either in large wooden hoppers (in capacities from 70 to over 200 cu. yd.), at No. 2, 3, and 4, or directly into a large mud-box at the head of the string of sluice-boxes, as at No. 5.

The dump of pay-dirt at No. 1 was piped or hydraulicked down with a giant or nozzle, and the concentration or bottom of the dump was shoveled into sluice-boxes by manual labor, and the tailing was removed by horse teams and scrapers. This work was conducted day and night continuously until completed. At properties No. 2, 3, and 4 the pay-dirt was sluiced intermittently, whenever the hoppers were filled, or about once each day, and at No. 5 the pay-dirt was sluiced as fast as it was hoisted and deposited or emptied into the mud-box. The water required for sluicing purposes was in all cases supplied by independent distillate engines driving pumping plants, except at properties No. 2 and 3, which being worked together had one pumping plant in common.

At property No. 1 the pay-dirt averages 1 ft. above and 1½ ft. in bedrock. The deposit above bedrock appears to be an ancient sea bottom, and is composed of coarse gravel and sand with a great deal of white quartz and plenty of well preserved pecten shells. At properties No. 2 and 3 the pay-dirt averages 1¼ ft. above and 1¼ ft. in bedrock. The deposit above bedrock here also appears to be an ancient sea bottom, composed of sand, gravel, and boulders, with plenty of well preserved pecten shells. At No. 4 the pay-dirt averages 2 ft. above and 1½ ft. in bedrock. The deposit above bedrock is composed of well washed coarse gravel and sand. At No. 5 the pay-dirt aver-

ON LITTLE CREEK IN 1906.

| Mining | 127.44 | 118.30 | 94.31 | 101.09 | 104.51 |
| Shuicing | 63.90 | 17.25 | 13.75 | 12.47 | 8.57 |
| Grand total operating cost per cu. yd. of pay-dirt.... | 241.19 | 178.11 | 146.94 | 145.50 | 139.81 |
| Value of mining outfit | \$5,000 | \$7,500 | | \$2,000 | \$2,000 |
| Value of pumping outfit | 2,500 | 2,500 | | 1,200 | 1,000 |
| Total value | \$7,500 | \$10,000 | | \$3,200 | \$3,000 |

Columns No. 1, 2, and 3 refer to the Linda Association claim on Center creek; No. 4, Bench 1, Center creek; and No. 5, the Otter creek property.

ages 2 in. above and 2 ft. in bedrock. The deposit above bedrock is a fine or small black graphite-stained gravel, and sand in places.

The bedrock in properties No. 1, 2, 3, and 4 is a more or less broken-up mica schist. At No. 5 it is a broken-up black slate, which, when exposed to the air gives off a peculiar sulphurous odor. The waste or overburden at properties No. 1, 2, and 3 is a coarse gray sand; at No. 4 a light gray-brown sand and clay; and at No. 5, a fine light red gravel or gray sand.

All fuel used for thawing and hoisting in each of the cases hereinafter cited was California crude oil. The variation in cost of fuel noted in the annexed table is partly due to the fact that the initial price was raised during the last year, although the former and lower prices were maintained in some cases because of contracts which had not yet expired; and partly to

the different freight rates, which are proportional to the various distances between the supply station at Nome and the mines, and are lower during the winter than in the summer. The price of distillate at Nome was 23½¢ per gallon. The additional cost hereafter noted is due to freight charges.

The cost data tabulated above cover only the total operating expense during actual mining operations, and do not include interest on the investment, depreciation, or any expense incurred through prospecting or preparatory work.

1. Cubic yards thawed includes both pay-dirt and waste. Wherever reference is made in this article to cubic yards, the same is based on loose or excavated dirt, measured by the number of buckets of pay-dirt hoisted. The quantity of waste is estimated according to the relative thickness of waste compared with

the thickness of the pay-dirt in this case.

2. Number of men employed and cost per day for sluicing up the pay-dirt in No. 1 property cannot be tabulated. However, the following statement gives the total number of men employed and the total expense of sluicing all of the pay-dirt, amounting to 6520 cu. yd. hoisted during the winter: 10 men were employed per day during the ground-sluicing process and 21 men per day during the shoveling in process. The wages paid were \$6 per man per day on account of working 12-hour shifts.

3. Duty per man per day in cubic yards, exclusive of manager.

4. Duty per man per day in cubic yards, based on number of laborers only.

Repairs and renewals are in some cases closely estimated, no true records being available.

The large consumption of distillate while sluicing the pay-dirt on No. 1 property was due to pumping water continuously for 24 hours per day for 18 days and handling 6520 cu. yd. of dirt with a considerably larger volume of water than was necessary under the conditions obtaining as shown at No. 2, 3, 4, and 5 properties.

No. 2 and 3 properties had approximately twice the head to pump against that No. 4 and 5 had, which explains the greater consumption of distillate. Property No. 4 pumped intermittently, while No. 5 pumped continuously during the day shift, which explains the greater consumption of distillate of the later. Properties No. 2 and 3, being operated under one management, reduces the operating expense for No. 2 by 7.98c. and No. 3 by 6.35c. per cubic yard below what it would have been had each of these plants been operated independently; or, in other words, the total operating cost per cubic yard of pay-dirt of No. 2 and 3, if operated independently, would have been 186.09c. and 153.29c., in place of 178.11c. and 146.94c., respectively, as actually obtaining.

The following conclusions may be drawn:

(A) The cost of thawing is unquestionably higher during the winter than the summer season.

(B) Actual mining likewise is apparently more expensive during the winter than the summer.

A WINTER DUMP; THE BUCKET DROPS DOWN A VERTICAL SHAFT AND LOADS FROM A SUMP.

GROUND SLUICING A WINTER DUMP.

(C) Sluicing the pay-dirt mined and hoisted during the winter necessitates rehandling the dirt, which greatly increases the operating cost of winter mining. It is also evident that plants operating with hoppers require more labor than do those where the pay-dirt is deposited directly into a mud-box.

(D) The total operating cost proves beyond a doubt that winter mining is the more expensive. Preparing

or blocking out the ground in the spring, under the low winter rate of wages, and mining the gravel during the summer under the system of property No. 5, is the most profitable method.

(E) The pay-streaks herein cited average in thickness from 2 ft. 2 in. to 3 ft. 6 in., and the waste or

overburden necessary to be removed in order to provide head-room for the workmen averages in thickness from 1 ft. 6 in. to 2 ft. 4 in. It is therefore evident that the operating cost per cubic yard of pay-dirt will be materially reduced according to any increase in the thickness of the paystreak.

Eighty Years of the Silver Market

Owners of silver-producing mines in Australia, Canada, Mexico, and the United States keep a close watch on the prices of this metal and the causes of fluctuations. The following valuable table, compiled by Pixley and Abell, bullion brokers of London, shows the movements of the silver and causes thereof, from

1833 to the end of 1913. The average prices are in pence per ounce, and to convert into United States coinage multiply by 2. The imports and exports refer to transactions in London, which is the great market for silver. Quotations since the first of the year appear in our market pages.

| Years. | Average. | Imports of bars and coin. | Exports to the East. | Remarks. |
|--------|-------------------|--|----------------------|--|
| 1833 | 59 $\frac{3}{16}$ | | £1,895,023 | Continuance of East India Co. Slavery abolished, compensation to owners, £20,000,000. Renewal of bank charter, bank notes a legal tender. |
| 1834 | 59 $\frac{1}{16}$ | | 2,146,465 | Great importation of gold into New York. Substitution of metallic currency for paper in the United States. |
| 1835 | 59 $\frac{1}{16}$ | | 2,036,167 | Extinction of United States national debt. Bank of United States wound up, owing to refusal of Congress to re-charter it. |
| 1836 | 60 | | 2,610,101 | Banking and commercial embarrassments in United States. Spanish civil war. |
| 1837 | 59 $\frac{9}{16}$ | | 3,010,190 | Commencement of panic in London. Discounts refused. Many houses trading with the United States stop payment. Accession of Queen Victoria. Rebellion in Canada. |
| 1838 | 59 $\frac{1}{2}$ | No statistics of imports of silver obtainable prior to 1858. | 1,945,264 | Resumption of specie payments in United States. Famine in various parts of British India. Afghan war. |
| 1839 | 60 $\frac{3}{8}$ | | 1,786,253 | Banks in United States suspend payments in specie. War with China. |
| 1840 | 60 $\frac{3}{8}$ | | 1,841,335 | Misunderstanding with France. Treaty of London for settlement of Eastern question. |
| 1841 | 60 $\frac{1}{16}$ | | 3,143,292 | Great depression in every branch of manufacturing industry. |
| 1842 | 59 $\frac{7}{16}$ | | 4,794,678 | Peace with China. Income Tax Act passed. |
| 1843 | 59 $\frac{3}{16}$ | | 3,752,472 | Treaty of commerce opens China to all nations. |
| 1844 | 59 $\frac{1}{2}$ | | 2,495,959 | Bank Charter Act passed. Consols 101 $\frac{1}{4}$. Prior to September this year, the bank never reduced the rate below 4 per cent. |
| 1845 | 59 $\frac{1}{4}$ | | 2,939,922 | Railway mania. Sikh war. |
| 1846 | 59 $\frac{5}{16}$ | | 1,973,391 | Commercial and railway panic. Repeal of corn laws. |
| 1847 | 59 $\frac{1}{16}$ | | 4,204,503 | Year of panic. £10,000,000 granted for relief of famine in Ireland. Gold discovered in California. |
| 1848 | 59 $\frac{1}{2}$ | | 3,396,807 | Sikh war. |
| 1849 | 59 $\frac{3}{8}$ | | 3,811,809 | First importation of Californian gold into England. Annexation of the Punjab. |
| 1850 | 60 $\frac{1}{16}$ | | 5,052,059 | Average of consols 96 $\frac{1}{2}$. |
| 1851 | 61 | | 1,715,100 | Discovery of gold in Australia. |
| 1852 | 60 $\frac{1}{2}$ | | 2,447,450 | Consols touched 102, and averaged 99 $\frac{3}{4}$. |
| 1853 | 61 $\frac{1}{2}$ | | 3,117,980 | Australian mint established. |
| 1854 | 61 $\frac{1}{2}$ | | 3,095,490 | Russian war began. |
| 1855 | 61 $\frac{5}{16}$ | | 6,431,733 | Loan of 16 millions. Fall of Sebastopol. |
| 1856 | 61 $\frac{5}{16}$ | | 12,113,991 | Russian war ends. |
| 1857 | 61 $\frac{1}{4}$ | | 16,731,915 | Panic. Suspension of Bank Charter Act. Indian mutiny. Loan of £1,000,000 to East India Co. |
| 1858 | 61 $\frac{5}{16}$ | £6,700,000 | 4,753,933 | End of Indian mutiny. |
| 1859 | 62 $\frac{1}{16}$ | 14,772,460 | 14,828,521 | Loan of £5,216,528 to East India Co. |
| 1860 | 61 $\frac{1}{16}$ | 10,394,000 | 8,478,739 | Commercial treaty with France. |
| 1861 | 60 $\frac{1}{16}$ | 6,590,000 | 6,824,807 | Financial depression in India. American Civil War begins. |
| 1862 | 61 $\frac{7}{16}$ | 10,753,000 | 10,091,460 | Great distress in cotton manufacturing districts. Panic. |
| 1863 | 61 $\frac{3}{8}$ | 10,888,130 | 8,263,011 | Large exports of gold to the Continent to pay for silver. |
| 1864 | 61 $\frac{3}{8}$ | 10,827,300 | 6,254,004 | £13,000,000 silver exported from France. |
| 1865 | 61 $\frac{1}{16}$ | 6,980,000 | 3,598,058 | Close of American war. |
| 1866 | 61 $\frac{1}{4}$ | 10,778,000 | 2,365,626 | Commercial and joint stock companies panic. Bank declined to sell bar gold. |
| 1867 | 60 $\frac{9}{16}$ | 8,020,000 | 642,912 | Great decline in export of silver, only £2,500,000 sent from France. |
| 1868 | 60 $\frac{1}{2}$ | 7,716,420 | 1,635,642 | Abyssinian expedition. |

EIGHTY YEARS OF THE SILVER MARKET—(Continued.)

| Years. | Average. | Imports of bars and coin. | Exports to the East. | Remarks. |
|--------|--------------------|---------------------------|----------------------|--|
| 1869 | 60 $\frac{7}{16}$ | £6,730,000 | £2,362,943 | Distress in Lancashire. |
| 1870 | 60 $\frac{9}{16}$ | 10,649,000 | 1,579,473 | Franco-Prussian war. Panics. |
| 1871 | 60 $\frac{1}{2}$ | 16,520,000 | 3,712,473 | £8,500,000 gold exported to Hanse towns. (Peace between France and Germany.) |
| 1872 | 60 $\frac{5}{16}$ | 11,140,500 | 5,654,451 | £8,050,000 gold exported to Hanse towns. (Commencement of decline in price of silver.) |
| 1873 | 59 $\frac{1}{4}$ | 12,302,220 | 2,497,576 | £10,000,000 gold exported to Hanse towns. (German Government announces the demonetization of silver.) |
| 1874 | 58 $\frac{5}{16}$ | 11,797,990 | 7,092,726 | Enormous increase of bullion in Bank of France, £22,000,000, mostly gold. |
| 1875 | 56 $\frac{1}{4}$ | 9,506,757 | 3,714,404 | Heavy commercial failures. Large export of gold to Germany. Continued decline in price of silver. |
| 1876 | 52 $\frac{3}{4}$ | 13,585,608 | 10,914,407 | Remarkable fluctuations in rates of Indian exchanges and bar silver. |
| 1877 | 54 $\frac{13}{16}$ | 21,625,652 | 17,007,458 | Great famine in India. Russo-Turkish war. |
| 1878 | 52 $\frac{9}{16}$ | 11,453,105 | 5,842,577 | General depression in trade. Large bank failures. Russo-Turkish war ended. |
| 1879 | 51 $\frac{1}{4}$ | 10,520,012 | 7,034,967 | Suspension of sales by German Government. Marked diminution in production of Californian mines. |
| 1880 | 52 $\frac{1}{4}$ | 6,827,471 | 6,135,520 | Consols touched 100 $\frac{3}{4}$. Reported existence of large quantities of gold in south India. |
| 1881 | 51 $\frac{11}{16}$ | 6,902,210 | 4,288,009 | Meeting of conference in Paris respecting bimetalism, which adjourned without coming to any practical conclusion. |
| 1882 | 51 $\frac{1}{2}$ | 9,243,375 | 6,423,270 | War with Egypt. |
| 1883 | 50 $\frac{9}{16}$ | 9,468,002 | 7,125,454 | Completion of Italian order for gold. |
| 1884 | 50 $\frac{1}{2}$ | 9,546,496 | 8,418,521 | War in Egypt, income tax increased. Franco-Chinese complications. |
| 1885 | 48 $\frac{1}{2}$ | 9,377,601 | 8,010,925 | Suspension of the coinage of the Bland dollar, recommended by the President of the United States. |
| 1886 | 45 $\frac{3}{8}$ | 8,166,249 | 5,846,222 | Great depression in trade. |
| 1887 | 44 $\frac{1}{2}$ | 7,471,639 | 6,327,113 | Depression in trade continued, assisted by war rumors. |
| 1888 | 42 $\frac{1}{8}$ | 7,825,380 | 7,807,400 | Deaths of two German emperors successively caused great uneasiness. War rumors subsided later. Stringency of money earlier than usual toward close of the year. |
| 1889 | 42 $\frac{11}{16}$ | 9,184,940 | 8,575,713 | Home coinage of silver unusually large. |
| 1890 | 47 $\frac{11}{16}$ | 10,385,659 | 8,456,709 | Serious panics in London and New York. Extension of silver legislation in the United States. |
| 1891 | 45 $\frac{1}{16}$ | 9,316,200 | 7,082,719 | Chilean revolution. Failure of United States Legislature to maintain silver prices. Large Continental orders. |
| 1892 | 39 $\frac{1}{2}$ | 10,746,382 | 11,881,885 | Further depression in silver. Inoperative monetary conference at Brussels. |
| 1893 | 35 $\frac{1}{2}$ | 11,913,395 | 11,649,411 | Indian mints closed to free coinage of silver. Report of Sherman Act. Australian bank crisis. |
| 1894 | 28 $\frac{15}{16}$ | 11,005,507 | 10,041,162 | Duty of 5% imposed on silver entering India. War between China and Japan. |
| 1895 | 29 $\frac{1}{4}$ | 10,669,682 | 6,484,933 | Speculation in African mines. Large indemnity to Japan. Consols touched 108 $\frac{1}{8}$. U. S. currency difficulties. |
| 1896 | 30 $\frac{3}{4}$ | 14,329,116 | 6,897,015 | Consols touched 111. Defeat of silver party in U. S. election. Extensive coinage of silver by Russia. |
| 1897 | 27 $\frac{9}{16}$ | 18,032,091 | 7,223,397 | Turco-Greek war. Famine and plague in India. Gold standard adopted by Japan. |
| 1898 | 26 $\frac{1}{8}$ | 14,677,799 | 5,949,285 | Spanish-American war. Indian Monetary Conference. European extension in China. Soudan reconquered. |
| 1899 | 27 $\frac{7}{16}$ | 12,727,989 | 7,742,829 | Boer war. 6% bank rate in December. Consols down to 97 $\frac{1}{2}$. |
| 1900 | 28 $\frac{1}{4}$ | 13,322,300 | 9,985,642 | Continuation of Boer war. Large coinage of rupees. Boxer rebellion in China. |
| 1901 | 27 $\frac{3}{16}$ | 11,501,678 | 9,018,419 | Death of Queen Victoria. Assassination of President McKinley. Continuation of Boer war. Combination of American smelters. |
| 1902 | 24 $\frac{1}{16}$ | 9,764,296 | 7,565,305 | End of Boer war. Heavy fall in silver. War indemnity unsettles China trade. |
| 1903 | 24 $\frac{3}{4}$ | 10,310,330 | 8,051,780 | Straits Settlements and Siam adopt gold standard. Large purchases by the Indian Government. U. S. buys for new Philippine coinage. Mexican Currency Commission. |
| 1904 | 26 $\frac{1}{2}$ | 11,687,339 | 10,038,319 | Russo-Japanese war. Monetary reform in Mexico. Continued buying by Indian Government. |
| 1905 | 27 $\frac{13}{16}$ | 12,992,014 | 8,643,405 | Mexican mints closed to free coinage of silver. End of Russo-Japanese war. Internal troubles in Russia. Continued buying by Indian Government. |
| 1906 | 30 $\frac{1}{2}$ | 17,288,063 | 15,565,334 | Heavy purchases by Indian Government. Large exports of dollars from Mexico. Resumption of purchases by U. S. Government. Straits exchange fixed at 2/4 per dollar. |
| 1907 | 30 $\frac{3}{16}$ | 15,983,892 | 12,752,230 | Cessation of Indian buying. Sharp fall in silver. Financial crisis in U. S. Bank rate 7%. |
| 1908 | 24 $\frac{1}{2}$ | 10,326,889 | 10,243,968 | Large gold exports to Paris. General depression in trade. Political unrest in southeastern Europe. |
| 1909 | 23 $\frac{1}{16}$ | 11,814,889 | 8,936,715 | Some improvement in trade. Good crops, especially of cotton in India. |
| 1910 | 24 $\frac{1}{2}$ | 14,100,310 | 8,648,443 | Death of King Edward VII. Indian import duty on silver increased from 5% ad val. to 4 annas per ounce. |
| 1911 | 24 $\frac{9}{16}$ | 14,293,747 | 9,865,796 | Strikes and labor unrest in England. Rebellion in China. Italian war in Tripoli. |
| 1912 | 28 $\frac{1}{2}$ | 16,778,304 | 14,345,474 | Establishment of provisional government in China. Indian Government purchased £6,000,000 silver. War between Turkey and Balkan States. |
| 1913 | 27 $\frac{9}{16}$ | 14,495,049 | 10,739,978 | China loan of £25,000,000. Indian Government bought £5,500,000 silver. Failure of Indian Specie Bank. Civil war in Mexico. |

Assembling and Erecting Wooden Tanks

By J. M. LILLIGREN

Redwood tanks are an important part of the equipment of many reduction plants. The general features connected with the erection are familiar, but in the making of a good tank there are many details known only to those who have had the experience. Particularly is a knowledge of details essential in erecting a tank with warped material.

The first important consideration is the selection of material. Whatever the number and size of tanks may be, the contract with the mill should call for well seasoned material because this class and no other will give the best results. The manufacturer generally turns out first-class stock, and the shipments leave the plant in good condition, whether seasoned or unseasoned. Owing to the softness of the wood, the transfer and haulage to the mine or mill should be under intelligent direction to avoid damage. When the material arrives at its destination it should be piled and protected from rain, snow, and direct sunshine to prevent shrinkage and warping. Where possible, the mill furnishing the redwood delays shipment purposely so that the material may have no chance to check, warp, shrink, or become water-soaked. However, it is not always possible to arrange shipments to out-of-the-way places so that material will arrive as used, and some warping and shrinkage will usually occur, especially in wood not properly seasoned. Warped material adds greatly to the difficulties of erection, and as the minimum of twist is met with in well seasoned stock, the necessity of specifying this grade in ordering, and taking proper care of it at the plant afterward, will be appreciated.

Foundations

The foundation may be either of timber or concrete, but whatever class is used there are two essentials to be observed. First, that the tank bottom be supported by chime joists or stringers, at intervals of not more than 30 in. for tanks about 12 ft. high, and 24 in. for 20-ft. tanks. The joists may vary in size, though it is customary to use 6 by 8-in. or 6 by 10-in. timber. The centres for joists on tanks of different size can be proportioned from the two given as the height of ordinary tanks does not often run above 20 ft. The limit of distance apart for low tanks can be considered as 36 in. The second essential to be noted is carrying the joists out to within at least 3 in. of the stave chime; all should be level, and without projecting nails. The foundation should be built up sufficiently high to give plenty of room under the tank for free circulation of air. Rot is the most deadly enemy of redwood tanks, and if the circulation of air is not provided the life of the tank is materially lessened.

Laying Out Bottom

With the bottom supports sufficient in number and properly spaced and cut, the next step is laying out the bottom. The line from which the work starts is struck at right angles to the joists and marked across all of them by pencil. The line is determined by first finding the exact centre of the foundation, and then measuring from this point a distance equal to the distance of the trammel mark from the edge of the centre plank. The trammel mark is a point on the centre plank and is the centre of the tank bottom; it is made at the mill at the time the bottom is laid out for cutting. Any convenient piece such as a 2 by 4 in. is nailed flush to the line to serve as a backing in laying the first half.

Bottom planks are generally marked with a letter and number, the letter denoting the tank, while the number gives the position of the plank starting from one side. When bringing in the bottom pieces they may be placed roughly in their respective positions, piling three high to allow room to lay out the centre; this also permits the guard pieces at each end to be conveniently knocked off. The two outside pieces, known as cants, are carefully placed to one side to avoid injury, as the points, being slender, are easily damaged.

Starting from the 2 by 4 in., the planks are laid on both sides as their numbers indicate, snugly against each other. This is to observe any warping or wide cracks. When planks are in two pieces, as they generally are in large tanks, they should be of exactly the same width where they butt together. When they are not, they are taken up, scribed, and dressed down to the line with a plane, the finishing being done with a jointer.

In finishing a plank, the outer end should be slightly wider than the butt, because in tightening up the tank after the staves and bands are in position a tight joint is assured at the ends of the bottom pieces. If the pieces are true, a tight joint will result along the entire length of the plank, but if a difference in width makes it necessary to dress down one or both, it is best to have a very light taper run from butt to outside end; the difference in width between butt and end is taken care of when the bottom is drawn together.

When a small amount of water is first put in a finished tank the bottom may have a tendency to lift up at one or more places due to the crosswise swelling of the planks. In a measure, the spring of the bottom can be almost entirely avoided by cutting out about three-eighths of an inch from that plank which is distant about one-sixth of the diameter from each end-piece; tapering the cut from centre to outer ends

should be carefully observed. This is illustrated at *a*, Fig. 1. At first glance it would seem that cutting out this amount from the piece would leave an open seam, but the fact is that the tightening process brings the pieces together to a good joint, and in the subsequent swelling there is less tendency for the bottom to rise.

When all the bottom planks have been carefully looked over and trued up, the pieces are again roughly piled to make room at the centre, and the work started of laying the bottom permanently. Beginning at the

FIG. 1.

centre and on that side of the centre line from which the numbers start, the two centre planks are laid down snug against the strip, the outer ends equally distant from the joists. Wooden pins are then inserted in the dowel holes, and the next set plank laid on to a close fit. Where two planks form one bottom piece, the butts are sawed for inserting a flat iron or wooden slip tongue. Care must be used in driving the iron ones, as there is a chance that they will run either up or down, thus making a bad butt joint. Wooden slip-tongues are preferable to iron, for the wood will swell and give a tight joint. If there is need for driving the plank to make a close fit, a block of wood should be used as a buffer; under no circumstances should the edges of the plank be struck with a hammer.

Laying the pieces, proceed until all of the first half is in place. This is then tied together by nailing a piece of 2 by 4-in. timber from cant to centre at approximately right angles to the lengths, the purpose being to hold this half of the bottom until the second half has been laid. The strip marking the centre line is then removed and the balance of the bottom put in place. The entire bottom is then tied together with a second piece of 2 by 4-in. timber. A line is then scribed around the rim of the bottom the depth

of the croze, to serve as a mark for determining when the staves and bottom come together.

Setting Staves

The diameter and height of tank determine the character of scaffolding required in setting up the staves. This is largely a matter of individual taste, but the scaffold should be strong, well braced, and with platforms at suitable heights for convenient and rapid work. On low tanks, and even on tanks of considerable height, where the staves are all quite straight, it is possible to do the erecting without a scaffold by toe-nailing the staves to each other from the inside, and using the usual inside bracing. However, as a matter of general safety, it is best to use a scaffold on all tanks higher than eight or ten feet. The arrangement of staves preparatory to erection depends upon the proportion of height to diameter. If the diameter is considerably greater than the height, the staves are laid on the finished bottom in eight piles, as shown in Fig. 2, four consisting of 'straights,' two

FIG. 2.

of 'lefts,' and two of 'rights.' The warp of a stave, looking at it from the inside chine end, determines whether it is 'right,' 'left,' or 'straight.' Fig. 3 illustrates this in a somewhat exaggerated form.

A glance at Fig. 2 shows the straight staves are so piled that they can readily be set up at each of the cant pieces, and at opposite sides of the centre. There are several reasons for so placing them. The rim of the cant pieces are the weakest parts in the bottom, and partly because of this the straight staves are used, as they can be set very close together and held in position with the least strain on the rim. It is essential that straight staves be provided for opposite sides of the centre, because between each section the 'rights' and 'lefts' are erected.

Fig. 3 shows 'right and 'left' staves on opposite sides of a straight one. If a number of staves of the same warp were set up each side of a section of

straight staves, as shown in Fig. 4, there would be a tendency, when the tank is tightened, to pull one way and thus give a lop-sided tank; whereas, when they are set up as shown in Fig. 3, there is an equal

FIG. 3.

FIG. 4.

pull on both sides of the straight staves. If there is a preponderance of 'rights,' which is likely, more care must be used to insure an acceptable tank. If the length of a stave is too great to permit piling them on the bottom, they are set on end against the scaffold or placed outside around the bottom within easy reach. In any event, they are to be set up according to the diagram in Fig. 2.

If the staves are not marked at the mill, from 15 to 18 straight ones are selected for use in marking the position of the bands. The distance apart of each band is marked with pencil or chalk, and as the erection proceeds these staves are set in at more or less regular intervals. The placing of the bands is thus easily and rapidly done.

Obviously, the first stave set in position should be straight. To be assured the staves will not fall in while being set and before enough bands are on to hold them, it is usual to set them out of plumb in the proportion of 4 in. to 12 ft. in height, as shown in Fig. 5. A side brace is nailed to the first stave only, while the inside braces are nailed on at regular intervals until all staves have been placed in position. The braces serve the purpose of steadying the staves and overcoming any tendency of pitching in. Narrow strips of wood are laid on the stave tops and nailed, holding the stave in position after being set. The member of the crew whose duty it is to do this also takes care that the alignment and spacing of the tops is correct.

The stave croze is so cut that it will slip over the

FIG. 5.

rim one-third its distance, as indicated at *a*, Fig. 5, and a tap with a hammer drives it in half its depth, which is the proper distance in first setting the stave. This proves true only of properly seasoned and well cared for material. In poorly seasoned stock, or that which has been exposed to rain or sunshine, the croze may be large or small, depending upon conditions. If large, it becomes necessary to insert a strip of canvas or burlap to care for the shrinkage; if small, the edge of the croze must be battered a little. In the latter case there is danger of the chine breaking off; while in the first case there is a good chance that leaks will develop. All of which emphasizes the necessity of getting the right material in the first place and taking care of it afterward.

A very important matter is to encourage a uniformly close contact between all the staves, which is absolutely necessary in getting a tight tank. The staves are always set as close together as possible, especially on the cants, and when pulled in by the bands, draw closer until the stave and rim touch; if drawn more than this, the wood is crushed. The line previously scribed around the circumference is a good indicator for determining when the stave is up. The

compression gained by drawing the bottom plank together affects the staves at the ends of the plank, but does not have an equal influence at the cant pieces. At each of these the staves are brought closer together by providing four pressure points, as shown in Fig. 1. When the staves are being set, several of the bottom planks are opened a little at the ends and a thin wedge or shingle slipped into the seam, particular care being taken that the staves are set very close at each of the four points. Later, the shingle or wedge is removed. When the staves are finally drawn in by the bands, and the bottom planks come together, the staves at each of the four points exert a pressure upon the staves to each side. The point of least resistance is along the smoother rim of the cant pieces rather than along the cross grain of the plank ends, and consequently the staves at the cants are moved to a close contact.

Even when considerable care has been taken in setting the staves and drawing up the tank, small openings may be observed near the bottom. If they are few, a simple and effective emergency remedy is to drive a chisel into the stave from inside about one-half inch from the edge. This presses the wood out, closing the opening; a redwood wedge is then driven into the chisel mark and the opening permanently closed. If there are several small openings together, the procedure is to cut a short length of 4 by 6-in. lumber to fit the diameter of the inside. Placing this block on the bottom and against the side of the tank, it is beaten with a hammer from a point where the staves are tight toward the openings. The staves will 'work' in the direction of the open spaces. The bottom bands must be loosened to give the staves room to spring out and move. When this has been done, and the bands are finally tightened for the last pull, the joints will come together tight.

Banding and Trimming

Putting on the bands begins immediately after the last stave is in place. The second band from the bottom is the first to go on, and when drawn up snug will usually hold the staves in position. Before the inside braces are knocked off, a second band is put on about three feet above the first. If the staves flare out too much to allow this band to come together, the connection is made by using a short bolt and lug, the extension being removed later. With two bands on, the braces and top strips can be removed, and the staves drawn together to approximately a vertical position, after which the bands are put on in regular order.

The marked staves indicate the position of the bands, and each full band is made up of several sections, the number in each depending upon the diameter of the tank. The line of the lugs connecting the sections should be carried up at a uniform angle. If the lugs were placed directly one over the other, forming a vertical line, there would be one stave each side of the lug that would not be touched by the band. As

a result, when the bands were drawn up, the untouched staves would buckle, leaving open joints. When the lugs are carried forward and upward progressively, all staves are in contact with some of the bands and there is no inclination to buckle. The threaded end of each section should project through the lug to the left, as this gives a downward pull in tightening the nuts; a matter of some importance from the viewpoint of labor saved when it is considered that there may be as many as 300 nuts on one tank.

When several bands have been placed in position and drawn fairly tight, trimming the staves begins. This is done with a block of hard wood and a hammer. Starting at the bottom, the staves are beaten into position all around the tank, care being taken from the first that the staves come together without a staggered or saw-tooth effect. As the trimming proceeds upward, the bands above are kept just tight enough to permit working the staves into place by light blows of the hammer. Some staves may be bowed enough to require beating from the inside, but it is usually possible to work them out by hammering the adjoining staves alternately. With bands at proper tension, a light blow on the block is more effective than a hard one.

By the time the tank has been trimmed, all the bands will be quite tight, and everything about ready for the final pull. During the time the bands were being put on and when the tank was assuming final form, any tendency to list should be remedied by bracing the side opposite and drawing up the bands on that side; this pulls the listed side into position. All sections of each band should be tightened uniformly. When all is complete, the final tightening of the bands begins at the top and ends at the bottom.

Cone Bottoms

Cone bottoms are put in tanks to facilitate sluicing out whatever may be put into them. The use to which the tank will be put determines the pitch of the cone, which may vary from very flat to 45° or more. A few years ago cone-bottom tanks were made in such shape that the cone was watertight and supported the entire weight of the contained material. Present practice is to put the cone in on top of the flat bottom and leave space between the staves so the weight of the material will be on the well supported flat bottom and not on the cone.

Fig. 6 shows three ways in which the cone may be arranged. The first, 'A,' is generally used, as this does not involve a special stave. The opening between the staves at the circumference of the tank should be sufficient to allow the material going into the tank to settle through freely. The number of rings supporting the cone varies with the diameter; a 20-ft. tank may be supplied with one or two, while in a wider tank there may be three. The rings are made up of segments cut from 2-in. lumber and are 4 in. wide. As a rule, the number of segments to a ring are marked on several of the pieces, so there will be

no confusion in getting the right ones for the different diameters. Before laying out the segments the circle is marked on the tank bottom and the ring built around this mark. The ring supports may be either of 2 by 4-in. or 4 by 4-in. lumber; the weight to be supported is not great, but the supports should

FIG. 6.

be well nailed to the ring and bottom to overcome the buoyancy of the wood. When the ring is raised and the supports put under, the circle indicates the position very readily. The second arrangement of staves, shown at 'B,' is sometimes used. This involves a

out. This gives a good opening and one large enough for all purposes.

A cast iron cone for the bottom is usually provided (b. Fig. 7), and to this the staves are fitted. If no casting is furnished, the points of the stave can be protected by fitting on a flat iron ring. A ribbon of 1 by 4 in. nailed around the inside of the tank (a. Fig. 7, and Fig. 6) supports the ends of the stave. All staves are well nailed to the rings, and the ends are nailed to the bottom and sides of the tank.

In concluding these notes, it is well to emphasize the necessity of specifying the class and condition of material when ordering tanks, irrespective of size or number. If the proper foresight is observed at this time, and due precaution taken in handling the material later, little trouble will be experienced in erecting satisfactory tanks. The wood should be clear, straight grained, containing no knots, sap, or gum-holes. If possible, it should be from air-dried lumber, as kiln-dried material does not possess the 'life' found in the other. The ends of all staves and bottom pieces should be painted with an air-tight paint to prevent shrinkage and rot. The bottom planks should be cut from long lengths, and the ends well guarded against damage. It is well, also, to have the chines nailed, as they are easily damaged and not very easily patched up. These are the important points for consideration; by keeping them in mind from the first, a great deal of time and labor will be saved.

Costs at the Mexican Mill

This plant operates at Virginia City, Nevada, and gave the following results during the year ended October 31:

| | |
|---|--------------------|
| Ore treated, tons | 29,247 |
| Value of heads, gold, ounces per ton..... | from 0.156 to 1.19 |
| Value of heads, silver, ounces per ton..... | from 5.09 to 21.45 |
| Extraction, per cent | 89.29 to 93.44 |
| Gold recovered, ounces | 17,879 |
| Silver recovered, ounces | 322,758 |

FIG. 7.

long and short stave. The area of openings is larger than in the first arrangement and is equally efficient in letting the material settle through to the bottom. 'C' shows a somewhat similar arrangement to 'A,' only in this case each stave is cut about two-thirds its length and a strip about one-half inch wide taken

Lead Smelting at East Helena, Montana

By BANCROFT GORE

Investigation of methods to overcome silver-lead losses in fume discharged into the atmosphere from pot roasting and Dwight-Lloyd sintering departments was under way at East Helena in 1913, use being made of an experimental baghouse in the hope that the gases from these departments could be filtered as in the case of the blast-furnace fumes, without destruction to the cotton bags. The long life of the bags for the blast-furnace is said to be due to the very low temperature of the gases (so low that during very severe winter weather, recourse is had to preheating them at entrance to baghouse to prevent freezing of the cotton fabric) and to the neutral character of these fumes, the greater part of the SO_3 being neutralized by the excess of lead and zinc oxides. An important clue to this smoke problem was discovered when an attempt was made to obtain a good mechanical mixture of the gases from the two departments. The resulting mixture, due to lead content of gases from the sintering department, gave favorable results with the experimental bags, and there is little doubt that during the present year all these fumes at present escaping will be diverted to a separate baghouse. This improvement will not only bring in a large revenue each year in the form of silver-lead recovered in the baghouse fume, but will eliminate any possible claims for damages from owners of adjacent agricultural land, which is fast becoming valuable for intensive farming, under irrigation.

Blast-furnace work at this plant has reached a high degree of perfection, in spite of the difficulties arising from the extremely high content of lead in material smelted consisting mainly of concentration products from the Coeur d'Alene lead mining district in Idaho. It is a pleasure for anyone who has tried to get good work out of a blast-furnace feeding it any kind of material that happened to be on hand, such as raw flue-dust, fine ores, crude slime, mud, pasty briquettes, and other rubbish, to see these furnaces running along so merrily on 'predigested food' in the form of sintered and semi-fused products from the pot-roasting and Dwight-Lloyd sintering departments.

These products, along with some coarse oxidized ore, slag-shells, and a little limerock with some scrap iron and occasional fragments of receiver-bottoms, make an ideal mixture for the blast-furnace, giving it a high capacity, even sinking of the charge, clean, cool shaft, with fire showing in all the tuyeres. It has been found that under present conditions more material can be smelted with less fuel in three blast-furnaces than was formerly handled by four when treating crude or unsintered material.

An interesting attempt was made to adapt the trapped slag spout of copper work to the local con-

ditions, eliminating the labor of intermittent tapping of slag and matte. Owing to the heavy flow of matte and slag from these furnaces, this would have been a most desirable improvement. The first trial proved a failure, and the spout was removed, but its defects in design were made clear, and whenever a good opportunity is available, the spout, improved in design, will be tried again.

Contrary to predictions of many metallurgists, pre-roasting and sintering in pots has not been driven out by developments in the automatic sintering machines of the Dwight-Lloyd type. Each process seems to hold its own, the total product of pre-roasted material being about equally divided. It would appear at first sight that the labor needed to attend the pots, the constant vigilance needed to prevent blow-holes and accomplish even roasting, the intermittent operation of these pots, and the cost of breaking up the sintered 'buttons' would work out to their disadvantage. The contrary is the case, however, the automatic sinterers being used only for very fine material containing under 11% sulphur. The machines are very sensitive to slight variations in the charge, due probably to the lead content, which at times reaches 40%, and unless the analysis of the feed is kept within very narrow limits, the charge either fuses fast to the grates or passes to the stock bins with a large proportion of fine material and crude charge. The pots find favor because of their less exacting requirements, the material fed being somewhat coarser than that sent to the machines, with the exception of the fine roasted matte, practically all of which goes to the pot roasters.

One of the difficulties incidental to the automatic roasters was the clogging of the herring-bone slits in the grate bars. This was overcome at the East Helena plant by a simple but effective labor-saving device consisting of a heavy steel roller made up of individual sharp-edged discs spaced to correspond with the grate slits which were made to run parallel with the motion of the pallets. Heavy weights on this roller, which extended over the hearth a few feet ahead of the feed box, pressed the sharp edge of each steel disc into the corresponding hearth slot, forcing out any obstruction to the blast.

Coal in Chile costs from \$7 to \$8 per ton. Imported fuel pays no duty. The consumption of fuel oil is increasing, especially at nitrate works and mines. Fifty per cent of the oil comes from the United States, the balance from Peru, while 66% of the coal comes from England. During the first half-year of 1913 the consumption of fuels was as follows: domestic coal, 585,942; foreign coal, 653,667; coke, 23,050; and fuel oil, about 160,000 metric tons.

Increasing the Efficiency of a Grinding Pan

By JOHN RANDALL

The experiments here noted were conducted at the mill of the Beek Mining Co., near Atlantic City, Wyoming. The ore consists of a quartz mixed with tough hard schist with a variable amount of soft oxidized material. The mill has four Nissen stamps crushing in cyanide solution 26 tons of ore per day to 16-mesh screens, but various screens, some as fine as 32 mesh, have been used. The pulp from the stamps goes to a mechanical classifier, the sand from the classifier is discharged into a 5-ft. grinding pan, and thence formerly joined the slime in an agitator, and from the agitator went through a series of three Dorr thickeners for washing under the counter-current system. The product from the pan is thence returned to the classifier and travels in a closed circuit until ground fine enough to be classified as slime. I would state at the outset that the performance of the pan, although considerably improved, is at present by no means good, my reason for making this incomplete work public being that there are some details that seem instructive and likely to lead to further improvement by others.

Construction of Pan Tested

The pan as originally built had but four shoes and a solid ring die with no channels, and when first started was principally occupied in grinding iron, with little or no effect upon the ore. This construction was improved by D. C. Kelso, the Company's superintendent, by having a new muller and die-ring cast carrying 8 shoes and 8 dies with 1½-in. channels between.

Another important defect in the construction of the pan is that found in pans of a number of different makes, namely, that of connecting the driving yoke to the muller by means of 4 prominent lugs on top of the latter. These lugs act precisely like the vanes of a centrifugal pump to induce a strong outward current over instead of under the muller and shoes, this action being clearly discerned in this case by the wear in the top of the muller. It no doubt tends to reduce the circulation of the pulp under the shoes. As this defect could not be remedied without considerable expense, it was allowed to remain.

With the improved shoes and dies the pan was sliming 1.7 tons of ore per day to 150 mesh when I took charge of it in August 1913. The desirability of decreasing the amount of sand going to the thickeners and securing better gold extraction was the chief incentive to a study of its operation. No further changes were made in the pan's construction, but the usual plowshare-shaped baffles set around the sides of this as well as most other pans were taken out. These baffles were found to be unnecessary, as the pulp thrown outward by the shoe channels rises up

the sides of the pan and is forced to return to the centre, this vortex action seeming to be more regular without the baffles. A very heavy and elaborately made cast iron feed hopper was also removed as being wholly unnecessary and adding too much weight to the shoes. No changes were made in the speed of the pan, which runs at 68 r.p.m. Experiments were then made in running the pan on thick pulp, my theory being that thickening the pulp would cause a greater number of sand grains to occupy a given space under the shoes and thus increase the grinding capacity. This produced surprising results, making an estimated increase in the duty of the pan of over 50% and greatly lessening difficulties arising from sand in the Dorr thickeners. On this particular ore and with 16-mesh battery screens, which were then put on, as low as 30% moisture in the pan was found to be most satisfactory, a pulp thicker than this causing a higher consumption of power without any corresponding advantage. This amount of moisture seems very low, but was about 5% more than enough to fill the voids between the ore particles when settled without shaking. I am inclined to the belief that the proper amount of moisture for a tube-mill as well as a pan is not a fixed quantity as generally supposed, but depends upon the percentage of voids in the material. The amount of moisture going to the pan is regulated by adjusting the spray near the sand-discharge end of the classifier. Under these conditions, with the pan feed containing 82.6% on 100 mesh and 17.4% through 100 mesh, the pan product was 50.6% on 100 and 49.4% through 100 mesh. Moisture samples were taken from various points at and near the surface while the pan was in motion, and corresponded with that in the feed and discharge. Whether there was a zone below the surface containing more moisture or finer material was not ascertained.

Removing Material

All the sizings given in this article were made by panning the slime from the sample through the finest screen used until the sand was clean, separately drying the two portions, and then sifting the sand in the usual manner. The next improvement determined upon was a means of removing as fast as possible the 49.4% of fine material shown by the sizing of the pan product to be continually circulating under the shoes and occupying space there to no useful purpose. Accordingly, a 6-in. belt elevator with 5-in. buckets was planned to return the pan product to the classifier. The elevator was put in operation September 24, 1913, and since that time the pan has taken care of the entire product of the stamps with coarser

| | |
|------|-------|
| -150 | 58.1 |
| | 100.0 |

Subtracting the amount slimed by the stamps from the total amount slimed to 150 mesh, the amount slimed to 150 mesh by the pan is 17.8%, or 4.6 tons. This low duty of the pan to 150 mesh is offset by the fact that it is grinding all but 1.1% of the mill product to -80 mesh, allowing the entire mill tonnage to be treated as slime.

Data collected by Harley B. Wright in 1909 give the average duty of Kalgoorlie 5-ft. pans at 5.6 tons to 150 mesh. M. W. von Bernewitz has given the average duty of the same pans to 150 mesh at 7.5 tons, which no doubt represents improved practice in a country which probably has the best pan practice.

These investigations upon the pan at Atlantic City were incomplete when the mill was obliged to shut down on account of bad roads and consequent shortage of fuel which had to be hauled by wagon 38 miles. However, plans are under way for the improvement of the pan, the chief defect being the rigid connec-

battery screens, 16 to 10-mesh displacing the 20-mesh formerly used. It was found that the sand passing through the 80-mesh screen yielded good extraction, and, in order to make the classifier separate at this point, Mr. Kelso adopted the expedient of cutting a square notch 4 in. wide and 4 in. deep in the overflow weir of the classifier. The good classification thus effected at the desired point is shown by the following sizing:

TABLE I.—Sizing of slime overflow from classifier, being the entire mill tonnage as sent to the agitator and Dorr thickeners for treatment.

tion of the driving spider or yoke with the muller, causing the shoes to groove, wear rapidly, and consume an unnecessary amount of power. In this particular pan it seems to cause the shoes to chatter on the dies at times and consume nearly four times the necessary amount of power. This defect, although not in all cases producing such marked results, is found in most pans made in the United States. Indeed, I know of but one maker in the country, a firm at Colorado Springs, that builds a pan with the universal joint connection used in Western Australia. Two of these Colorado Springs pans, 5 ft. in diameter, are running at 42 r.p.m. at the Vulture mill, near Wickenburg, Arizona. Each is grinding 35 tons per day, 85% of the product being fine enough to pass through a 100-mesh screen. In reply to an inquiry on the pan subject, I have a letter from A. L. Bloomfield, superintendent at the Golden Cycle mill, Colorado Springs, in which he says: "The pans were a complete failure in Western Australia until the universal joint connection between yoke and muller was put on. Under no circumstances could you induce me to run a pan with the old rigid attachment."

The Freeman pan described by Mr. von Bernewitz in the *Mining and Scientific Press*, May 17, 1913, secures a good circulation and prevents slime from getting under the shoes by means of a cylindrical baffle fastened to the muller and extending above the level of the pulp, thus forcing all the unground material to pass under the shoes. There are various opinions as to the advantage of this arrangement, which probably depends upon other details for its success. In constructing a pan of this type, it is necessary that there should be no die channels, else the pulp will be thrown rapidly out through the shoe channels and return through the stationary die channels. It would also seem best that a pan of this type should have inward shoe channels which would leave the pulp-current under the shoes to be determined as much as possible by the feed alone and thus it would move so slowly as to give each particle of sand many chances to be ground before passing out. With good outside classification and a considerable amount of pulp moving in the closed circuit, so as to keep the amount of slime in the pan down to a low point, there might not be much advantage in the use of the baffle. The work of Mr. Söhnelein in changing a pan to this type and providing outside classification has lately shown excellent results, and indications are not wanting that the grinding pan is destined to make good in this country, particularly where small units are desirable. The slow progress so far made seems to be due principally to the fact that the construction which answered fairly well when pans were used for amalgamation has since been too closely followed where grinding is the object aimed at.

Thanks are due O. M. Beck, the manager, and Mr. Kelso, the superintendent, for permission to publish the results obtained at the mill near Atlantic City.

A New Battery Frame

A large volume could be published on the subject of battery frames, including those which have been suggested, those discarded, and those at present preferred. The constant effort has been to decrease the breakages inherent in the stamp-mill, and to gain greater efficiency in crushing. Including old and new installations throughout the world there are the following types of battery frames: 'H' and 'A' frame of cast iron; 'A' front knee, and standard wood frame; Nis-

WORKING MODEL OF STAMPS IN NEW BATTERY FRAME.

sen; Holman pneumatic; reinforced concrete and iron standards as tried at the City Deep on the Rand; and 'H' construction of box girders. Even this list does not include all. The question of foundations has been all important in the framing; but concrete is rapidly superseding everything else. Frames of wood are used in the majority of mills, but due to shrinkage of this material, and its being somewhat elastic, the breakages of cam shafts and stamp stems continue. Another fault in battery framing is the joining of ore-bins to the frame by timber which supports the cam and feeder floors, and is also supposed to be a means of stiffening the battery frame. Orebins are empty some days and full on others. Consequently, various strains are set up which result in the frame being pulled out of line, which eventually reacts on the working parts.

Many efforts have been made toward constructing a self-contained battery, and the accompanying cut shows such a type as designed by A. D. Foote of Grass Valley, and made by the Taylor Foundry & Engineering Co. The main battery posts are of cast steel weighing 4500 lb. each. They are bolted to a concrete

mortar block. The cross pieces, holding the guides, are planed at the ends to fit the posts accurately. The cam shafts are 6½ in. diameter; the stamps weigh 1250 lb. each, and have 3½-in. stems. Such a battery is self-contained, requires no support from orebins or by knee framing, and will have no 'give'. It should result in a small repair bill. Ten stamps constructed from this design are now working satisfactorily at the Tightner mine, near Alleghany, Sierra county, California. Results of the performance of this plant will be published when available.

Wet Crushing in Ball Mills

By A. W. ALLEN

The wet crushing Krupp ball-mill is a machine whose merits of high efficiency, combined with simplicity of operation, have hardly been sufficiently recognized. The mill itself does not differ materially from the machine used for dry crushing. In addition to the ordinary casing, the wet crusher is provided with a water spray which delivers over the whole width of the fine outer screening, just after the latter leaves the trough at the bottom of the mill. This trough consists of a spitzkasten in which the water-level is maintained at a fixed, but adjustable, level by means of a constant overflow. The discharge from the spitzkasten terminates in a 'gooseneck'; and nozzles of varying aperture are available for the purpose of regulating the percentage of water that goes out in the discharge.

A certain amount of classification takes place in the spitzkasten, and advantage may be taken of this fact by keeping the underflow separate from the overflow. As the mill revolves, a certain amount of water is caught and delivered into the centre of the mill, to assist grinding. At the same time the outer screening is kept clear, and an immediate discharge of ground product ensured by the large area of clean screening exposed, the operation being helped by the vibration of the mill. As in the dry-crushing machine, the power is conveyed through toothed gearing. The best work with the wet crusher is obtained on a uniformly compact ore, broken to about a 1½-in. ring. A coarser feed is only feasible with a friable ore. The wear on liners is high, but not disproportionate to the tonnage ground. A set of liners lasts about five months; and, under normal conditions, the additional steel consumption in a No. 5 mill amounts to about 16 lb. per 24 hours, this being the maximum weight of the balls used for grinding purposes. Outer screens last for several weeks without attention; and instances have been recorded where the mill has been run for some months without a shut-down for any cause whatever. The correct feed is determined by the sound of the mill, and the result of under or overfeeding is immediately recognized by the experienced millman. The feeder used is of the bumper type, and is capable of delicate adjustment.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—The wealth of detail in the series of articles by Mr. Horwood, together with the excellent photographs, makes local knowledge almost superfluous. I have read the articles with much enjoyment. At the same time, some points raised are not quite convincing, and, as the subject has been so fully and ably discussed by those with local knowledge, the doubts raised by an outsider or any healthy criticism may at least help to make the discussion interesting. The most striking statement, to my mind, is contained in the first 14 lines of the second column on page 965.¹ In the course of exploration and prospecting work, I have frequently noticed pyritic and other concretions in sedimentary rocks, under such conditions as to render the concretions devoid of economic importance, but I have had no difficulty in understanding their mode of formation, at least to my own satisfaction.

This matter of concretions has been fully discussed by J. E. Todd in a paper read before the Geological Society of America in 1903,² and, as the conditions prevailing during the mineralization of the banket and formation of buckshot pebbles are quite in accordance with those required by Mr. Todd, and are those generally accepted, I see no reason in straining after a more complex origin, and rather wonder that the paper in question has been overlooked apparently by Mr. Horwood.

By the courtesy of the curators at the Geological Museum, London, I have had an opportunity of handling at leisure, the specimen marked 'Rietfontein Mine A. Buckshot Reef,' presented in March 1905, by F. H. Hatch, and I noted that the pyritic pebbles are hard, irregularly disposed, and at times close together, though never actually coalescing. The conditions necessary for the formation of these buckshot pebbles, I take to have been: (1) A slowly moving solution because the pebbles are so very round, and this is further confirmed by Mr. Horwood's statement that the replacement of quartz pebbles by pyrite in many cases has been by equal volumes; (2) presence of nuclei because of the irregular disposition of the pebbles; (3) hot or concentrated solution—because the pebbles are so close together.

As to the nuclei, I have read Mr. Horwood's earlier paper on the mode of occurrence and genesis of the

carbon in the Rand banket, but from the method of collection adopted in the tests, it is impossible to say whether any of the carbon was originally present in the pebbles as nuclei, though it is possible.

In the summary on page 614,³ Mr. Horwood has evidently forgotten for the moment the definite rejection of the 'molecule for molecule' idea of Mr. Lindgren in the paper he quotes. Radiate structure is, of course, a common type of concretion. The growth of either type of pebble is quite simple, once a start has been made, but the starting is the interesting point, and any further information of a definite character as to nuclei in the one case or of the selection of particular pebbles for replacement, when there are so many others available, in the other case, will be welcome. There is, of course, an appreciable difference in the specific heat and conductivity of various kinds of quartz, as there is between one and another mineral, and if the mineralizing solutions were in a sufficiently critical state, these properties might be involved. However, there are other possible reasons for the selection of particular pebbles for replacement, and to these I shall now refer.

J. D. Irving says:⁴ "The least easily attacked rocks among the sediments are those containing high percentages of alumina," and R. B. Young, in discussing Mr. Horwood's paper on the carbon in the Rand banket, says: "There is abundant evidence all throughout the banket that aluminum silicates offer great resistance to replacement by pyrite, if, indeed, they are ever replaced at all, whereas no constituent is more easily replaced than quartz." He then goes on to give perfectly logical reasons why, owing to sub-capillary spaces in the quartzite, these pebbles should be singled out for attack. Against Messrs. Young and Irving, there is Mr. Horwood's statement on page 678,⁵ that "pyrite more readily replaces silicates, such as those of aluminum and the alkalies than it does quartz." In the absence of definite proof, the contention of Mr. Young and Mr. Irving seems more reasonable, and I would ask Mr. Horwood whether he has dissolved any of the replaced portion of these slaty quartzite pebbles and proved the absence of aluminum silicates.

Evidently there is an intimate genetic association of the gold, carbon, and pyrite, but, though the pyrite or the carbon, particularly the former, might precipitate the gold, the reverse may be, and possibly is, what happened in both cases, that is, the gold may have caused the precipitation of some of the carbon and of the pyrite, as indicated below. Mr. Young has recorded the association of much gold with a markedly unusual amount of tourmaline. Also he says that muscovite in sericitic aggregates or in large flakes is always present in banket showing coarse gold. With tourmaline and sericite, by reason of their mode of formation, we may associate gelatinous silica, and we then have a favorable medium for the concentration or collection of

¹See *Mining and Scientific Press*, December 20, 1913.

⁴'Replacement Orebodies,' J. D. Irving, 'Types of Ore Deposits,' page 251.

⁵*Mining and Scientific Press*, November 1, 1913.

gold,⁶ and one, moreover, that might account for some of the carbon. The carbon that lines the fissures and "does not soil the fingers" is probably deposited under pressure and at a considerable temperature in a manner similar to the 'gas carbon' deposited in retorts during the manufacture of illuminating gas.

I refer above to the authigenic tourmaline which, as Mr. Young says,⁷ forms the bulk of the tourmaline in the blanket, though there is some of allogenic origin.

In the matrix we also have a porous medium and one which could impede the diffusion of the reducing hydrocarbons, though not to anything like the same extent as gelatinous silica, and so, while we would have precipitation of the gold, it would be in a fine state of division, though not ultra-microscopic. Much of the blanket gold is in a fine state of division. I am seeking in this connection to establish a reason for the concentration of coarse gold with sericite and tourmaline; high temperature alone will not suffice, for the temperature, etc., necessary for the formation of tourmaline would be unfavorable to the deposition of gold.

I am aware that Messrs. Hatschek and Simon, in experimenting with gold, only precipitated pure gold, but they had precipitated various insoluble compounds, and there seems to me to be no reason why an alloy of gold and silver should not be precipitated, as has been suggested by A. N. Winchell⁸ in another case, under circumstances that might have prevailed at one time during the mineralization of the blanket. The enrichment of replaced slaty quartzite pebbles could be explained on similar grounds, the sub-capillary openings providing the porous medium inducing a preliminary deposit of gold previous to the replacement of the pebble by pyrite; or the incomplete replacement according as to whether pyrite does or does not replace aluminum silicate.

While on this matter of gelatinous silica, it is interesting to recall a paper by W. M. Courtis,⁹ in which he says, when trying to find some characteristic microscopic features of rich gold-quartz as compared with low-grade quartz: "From the examination of many rich gold-quartz specimens, the conclusion was formed that the quartz was in a gelatinous condition when the gold was introduced." Mr. Hatschek, in the paper already quoted, laid stress on the perfectly natural fact, and one previously recognized in the case of sandstones, that segregations in gels have a great tendency to form a spheroidal shape.

On page 721¹⁰ Mr. Horwood quotes J. P. Iddings, but Mr. Iddings would not obliterate the rough outlines of pebbles in the way Mr. Horwood suggests, for he (Iddings) says:¹¹ "Nor does it follow that curved,

or rounded, surfaces develop only through solution of plane-faced crystals. There may be interference with the regular development of crystal faces and plane surfaces due to irregularities of diffusion of crystallizing molecules and also to the viscosity of the liquid."

If the coloration of pebbles is due to chromium, and the presence of coloration is a measure of the richness of the blanket, then, an increase in chromium content should show a diminished gold content, for gold is much more volatile than chromium and would travel farther from its ultimate source before depositing; moreover, a marked increase of chromium would mean an end of the gold. If, as suggested on page 811,¹² the pyrite and gold were deposited from an eutectic mixture, we would expect a fixed ratio between the gold and pyrite. Does this exist?

Another point in connection with this eutectic mixture and one which, like the chromium, may be of immense economic importance, where such vast interests are at stake—and in any case is of great interest—before the eutectic point is reached one or other mineral is usually in excess and is deposited alone until that point is reached. If then the ratio of gold and pyrite in an eutectic mixture is determined, we should know that as soon as a point was reached in the lodes where the proportion of pyrite—presumably the mineral originally in excess—showed a marked increase, that point would mark the vertical limit of the gold in depth. In this connection it is important to differentiate between a mere decrease in assay-value of the lode, which might only indicate the approach of a poor zone, and an increase in the proportion of pyrite to gold. Mr. Young, in one of his papers, says: "In one case there is not only a ring of pyrite surrounding the carbon, but also another within the carbon itself." From this it would appear as though the mineralization was intermittent, that is, had been due to a pulsating action, and so the Rand in common with other gold-fields may yet experience alternating rich and poor zones and eventually will come to an end; when this will be, is a question for the men with local knowledge.

STEPHEN J. LETT.

Solution Control in Cyanidation

The Editor:

Sir—Mr. Allen, in his letter published in the *Mining and Scientific Press*, February 21, takes me as well as himself much more seriously than I do. My statements are in general qualified and I admit room for argument, upon which point only we seem to be in accord. My letter in your issue of October 11, 1913, is couched in the simple phraseology of the cyanide plant and does not admit of misconstruction by an operator. Any pretended misunderstanding as to the meaning of "zinc in solution" or "throwing away cyanide solution" is mere quibbling and evidently intended as a criticism

of the writing rather than of the matter under discussion. I would respectfully suggest that the argument, if continued, be limited to the question of "direct determination of free cyanide by titration with silver nitrate." My contention is that it can be determined with a fair degree of accuracy regardless of ordinary zinc content and alkalinity; and I further contend that conditions may exist which do not permit of the use of this or any other simple method. In other words, it might be impossible for an operator to determine free cyanide. I have been in such a position and venture to assume others have.

The success of this method depends largely on the ability of the operator to detect a very faint but definite change in the transparency of the solution. Mr. Allen's statement, "in the presence of zinc compounds there is no definite end point to be observed," would indicate that he neglected my "elementary" precaution to have flask and solution perfectly clear. Referring to quotation from Clennel's 'Chemistry of Cyanide Solutions,' this work was written many years ago, and I am inclined to believe that the quotation does not apply to the point in question. At any rate, the method has been used continuously for six or seven years at a plant which has been for a considerable part of the time under Mr. Clennel's supervision. Furthermore, it was E. M. Hamilton, who evidently enjoys the esteem of Mr. Allen judging from his complimentary reference, who first brought the method under discussion to my attention some six or seven years ago, and I know from personal association with Mr. Hamilton covering a period of years that he uses this method.

Does Mr. Allen still most emphatically disagree?

JAMES S. COLBYTH.

Los Angeles, February 25.

Revision of the Mining Law

The Editor:

Sir—I believe there would be a greater activity in prospecting if the United States mining laws were fashioned after the Australian mining laws.

Owners of all mining claims should be required to employ at least two men to every full claim of 600 by 1500 ft. The Australian law requires five men to each 25 acres. All mining claims should be in districts in charge of some mining warden or land office agent. The title should be in the form of a lease for 21 years; the lease renewable at the end of that time if the owners wish to continue work. If the owner does not comply with the working conditions of two men per claim for a period of 30 days, unless otherwise granted exemption by the warden, the claim should be considered abandoned and subject to re-location by giving notice to the warden and posting notice on the claim by the new locator. Re-location by old owners should not be allowed. All United States patented mining claims should be regulated by state laws compelling the owners to develop the ground.

I know that the miner or prospector at first will consider a law of this character severe, but in practice he would find that it has many advantages, and the state will be assured that its mineral resources are not being shepherded by those who will not develop them. The mining warden should have certain discretionary power, and in the case of the prospector who is anxious to develop his claim a working time limit could be given which would entitle him to exemption for six months.

The principal fault with the United States mining law is that it is too liberal, and the average locator of a mining claim has concluded that his title was secure when he put up his notice of location. He throws a stone at a point where he guesses his monuments should be, and files for record a statement of discovery which does not exist. The prospector who is honest in his location and does a certain amount of work on a fair showing has too often been discouraged and abandoned his claim, or sold it out to some local resident who holds the ground by a semblance of work or by false affidavits as to assessment work. I know of mining claims in California that have been held for 30 years, and the total value of the development during that time performed by so-called annual assessment work amounts to nil.

It is true that there is but little new territory to be explored by the prospector, and the young and venturesome have no change. The so-called 'grub-staker' or the grubstaked prospector did but little to develop the country. There are as many men as ever who are willing to do their own work and pay their own way if given a chance, and if protected by better laws when they develop a mine. The greatest trouble is that there are any number of good mining properties and undeveloped ground tied up either by the United States patent or unpatented claims, owned or pretended to be owned by people who will not develop the ground or let others do so.

The mining territories of the United States should be formed into mining districts, and the federal government or each state could well afford to keep up a court, including a mining warden, clerks, and mining surveyors, who for a small fee would adjust the mining claims and titles under the new law, so that the prospector would be protected in his claim so long as he performed the necessary work according to law.

In my mining experience, extending for a considerable time in Australia, I knew of no mining lawsuit as to the title of the ground, and no disputes but such as could be settled in the warden's court. In this country it is safe to say that no development or discovery is safe from any number of mining lawsuits, and the owners are often tied up for years on the questions of title. These conditions are all brought about by our poor mining laws and constitute a great disadvantage to the prospector.

H. C. CALLAHAN.

San Francisco, February 12.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

Slag produced at Mt. Morgan contains 45% silica.

Horse traction has superseded electric traction in the Mt. Morgan mine, as the latter system was too costly and a source of danger.

Of 2,113,080 tons of ore treated during the last quarter of 1913 by the Utah Copper Co., 56% was handled by the Magna, and 44% by the Arthur plant.

Stripping overburden at the Utah Copper Co.'s property during 1913, when 90% of the ore was mined by steam-shovels, amounted to 4,835,489 cubic yards.

Abrasive wheels, such as used in all machine shops, should be encased by steel plates, except at the point used for grinding, to prevent their flying and injuring mechanics.

Wage reductions to meet the cost of insurance under the Workmen's Compensation Act have been declared illegal by the California Industrial Accident Commission.

Carbidé ash, that is, carbide after having been used in a lamp, has a greater coefficient of friction than resin, and makes excellent dressing for a friction clutch that tends to slip.

Working time at the Great Cobar copper mines, New South Wales, allowing for Christmas holidays, Sundays, abstentions, and minor accidents, only amounts to about 290 days per year.

The deposit of niter on Camp creek, near Melrose, Montana, while probably not of commercial importance, affords an example of a nitrate deposit in a region having a fairly heavy rainfall.

Associated with lead ore on the 600-ft. level of the Shattuck-Arizona mine are small 'kidneys' of vanadium ore. Copper ore is also intermixed, and although a complex ore, a method of treatment is being devised.

Railroads caused nearly half the forest fires in Colorado and Wyoming last year, and nearly one-sixth were started by lightning. In California, lightning started more than half, with railroads a comparatively insignificant cause.

Saw-tooth buildings have a low cost when compared with any other type of building. Complete with cement floor and roof, the cost is about \$1 per square foot. This style of construction has the disadvantage

of not affording means for transport of material by overhead cranes.

Electricity plays an important part in the transmission of power in a modern cyanide plant. Tube-mills and other machines may be arranged irrespective of their position as regards line shafting, and ammeter readings are a valuable check on power consumption. They can be used as an indication of pebble load in tube-mills, or for the purpose of estimating the thickness of pulp in mechanical agitators.

Cup grease instead of white lead can be used with satisfactory and economical results in air-line connections. Cup grease costs less per pound and the amount used will be less in weight. In a large mine where air-lines are being constantly extended, changed, and repaired, the saving effected will be no small item. The economy in using some dressing in connections to prevent the threads from rusting tight is apparent.

Compressed air is a useful and often necessary commodity around a modern reduction plant. One of the reasons for its comparatively high cost is the fact that small losses around the mill are unnoticeable, although in the aggregate they may represent a considerable amount of wasted power. A contributory cause to such loss is the practice of laying compressed air mains and branch connections underground. Valve fittings and piping are liable to leak under such conditions and such loss is unavoidable and difficult to detect.

Pulp agitation by most systems yields a higher solution of metal with a higher dilution. A thick pulp generally means slow extraction coupled with increased horse-power for agitation. The preferable method is to agitate with a pulp of a thinness to give maximum solution in the minimum of time, afterward dewatering before filtration. The efficiency as well as the capacity of the filter is largely influenced by the condition of the pulp. With a thin pulp containing appreciable amounts of sand, the operation of filtration is slow and inefficient.

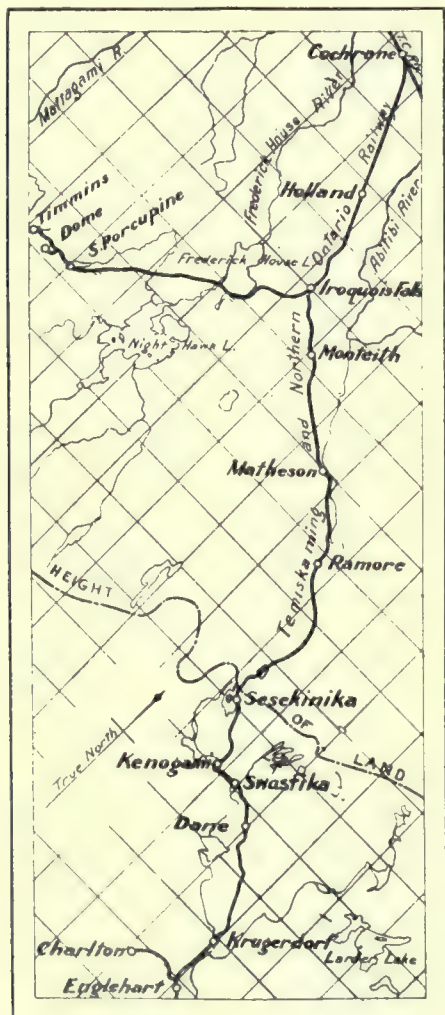

Troubles usually encountered in the working of a wet Krupp ball-mill are mostly due to a variation in the class of ore and to insufficient water-supply. Unless the ore is uniform, it will be necessary to give constant attention to the question of feed. A change from fine to hard rock without a readjustment of the feed will result in overloading the mill, with cumulative ill effects. On the other hand, it is necessary that the water in the spitzkasten be kept at the required level. To this end the box should be supplied with a valve operated by a float, connected with the water-supply, in addition to the ordinary equipment. Should the water-level in the box get below normal, there will be an immediate drop in output from the mill. As a result, the rate of feed will exceed the rate of output and the mill will rapidly clog up.

Special Correspondence

NEW YORK

TEMISKAMING COMPANY'S AFFAIRS.—TENNESSEE COPPER REPORT.
—GUGGENHEIM EXPLORATION DIVIDEND.—BUTTE & SUPERIOR
OUTPUT.—BRITISH COLUMBIA COPPER AFFAIRS.—IRON AND
STEEL. OIL AND GAS MEETINGS OF THE A. I. M. E.

A storm is brewing in the management of the Temiskaming. The annual report for last year showed gross receipts \$438,500 and a net profit of \$117,500, dividends during the year amounting to \$75,000. There is much dissatisfaction with this lean shaving, and Hamilton B. Wills will lead a movement for a change of control. He calls attention to the fact that the present directors only hold together 1375 shares out of the total of 2,500,000, and urges that the interests of the Company will be better served if its management is in the hands of men who have a larger interest in the Company than

PART OF THE ONTARIO MINING DISTRICT.

in the stock market, and that a larger representation of mining men is necessary. The mill is now treating 100 tons of ore per day, and it is stated that the total gross cost per ounce of silver produced is 42 cents. There would certainly seem to be room for improvement in this, and it is openly intimated that any new management could certainly do as well as the old.

The Tennessee Copper Co. has made its annual report, showing an output of 17,797,338 lb. copper, at a cost of 10.2c. per pound or \$2.93 per ton of ore. Of this, 4,257,822 lb. was from custom ore. The acid production was 197,713 tons. The gross receipts of the Company were \$1,158,503, net profits \$966,000, and dividends \$450,000, the total surplus now being \$1,865,000. The announcement was also made that the contract with the International Agricultural Corporation had been modified, so that the excess of acid not required by that Company will hereafter be marketed by the Tennessee company. There has been much discussion over this contract, some of the International shareholders complaining that they were burdened with a white elephant in being obliged to take all the acid the mining company could make, while the latter people point out that they have handled it all right so far. The matter is settled now, anyway. Utley Wedge has succeeded E. H. Westlake as vice-president, pre-
saging closer relations with the Pennsylvania Salt Manufacturing Co., that may perhaps open another market for the Tennessee acid. Mr. Westlake has been active in the gold-mining interests of the General Development Co., and now that it has sold its dredging property in Colorado it may be that this Company is planning to give some active attention to South America, especially Colombia, where it has been dabbling in gold properties.

It is reported that the Guggenheim Exploration Co. will increase its dividend rate to 14%, or \$3.50 per share. Certainly the Company has been doing well, and it has a surplus of \$24,811,000 over its \$20,800,000 in shares outstanding.

The Butte & Superior continues to do well, and it is stated that the output for February will be 10,250,000 lb. of zinc, 260,000 oz. of silver, and 500 oz. of gold.

British Columbia shareholders seem to be in a good deal of a fog as to what is going to happen to them after they pay over their \$1 per share for the new debentures of the Canada Copper Corporation, and exchange their stock. In a recent circular, Newman Erb assures them that the British Columbia has no money in its treasury, and unless they do fork out it is likely to lose its options on additional property and therewith the money that has been spent on them. Under the circumstances the minority shareholder feels very much in the position of the Presbyterian: 'damned if you do, and damned if you don't.'

At the morning session of the iron and steel meeting of the American Institute of Mining Engineers, held on February 18, Albert Sauveur presided. The first paper was by H. M. Howe and A. G. Levy, entitled, 'Notes on Plastic Determination of Steel During Overstrain.' The paper was essentially a series of fine and instructive microphotographs with explanations by Mr. Howe. The discussion was opened by R. C. Carpenter, of London, who spoke at some length and called attention to the work of Mr. Beilby. Brief remarks were also made by H. D. Hibbard, Mr. Webster, W. S. Lindgren, and R. H. Sweetser, and the discussion was closed by Mr. Howe. The exchange of international pleasantries between Mr. Carpenter on one side and Mr. Sauveur and Mr. Howe on the other side, added to the good feeling. A. Sauveur's paper was 'Notes on Some Heating and Cooling Curves of Carpenter's Electrolytic Iron.' The discussion by Mr. Carpenter and Mr. Howe centred around the real existence of the point A2 in the iron diagram. J. E. Johnson, Jr.'s paper dealt with the 'Influence on Quality of Cast Iron Exerted by Oxygen, Nitrogen, Etc.' This was probably the most sensational paper of the session. It was discussed at considerable length. Mr. Johnson showed a series of microphotographs, always two side by side, the two being of the same chemical composition with the only exception that in one the oxygen content was higher than in the other. In all these pairs of diagrams the iron with the smaller oxygen content showed the graphite in large flakes, indicating little strength, while in the iron with the higher oxygen content

the graphite was broken up into smaller particles so as to give a much stronger structure. The discussion was opened by R. Moldenke, who said that he agreed with much that was in Mr. Johnson's paper, but that he could not agree with the main result that oxygen is beneficial. Mr. Hibbard and Mr. Webster spoke briefly. Mr. Howe thought that Mr. Johnson simply claimed that not the oxygen itself, but the accompanying reduction of the graphite from large flakes to smaller particles, was the really beneficial element. John Howe called attention to the new test figures given by Mr. Johnson which were not in the published paper and which appeared to strongly confirm Mr. Johnson's claims. Bradley Stoughton answered R. Moldenke and expressed himself as being impressed with Mr. Johnson's results. In Mr. Johnson's microphotographs the irons with more oxygen have a better structure. The oxygen may have an influence in throwing the eutectic point to the right, though there is no evidence to that effect, but only inference. W. Campbell suggested a possible means through which throwing out of the graphite (resulting in the all-important structure) might be affected by the oxygen content. Mr. Sweetser and Mr. Hibbard spoke briefly, and Mr. Johnson concluded, describing how recently he had actually improved iron by adding oxygen.

B. Hopkinson and Sir Robert Hadfield's paper covered the 'Research with Regard to the Non-Magnetic and Magnetic Conditions of Manganese Steel.' In the absence of the authors, the paper was read by J. W. Richards. It was discussed by W. S. Potter, A. Sauveur, H. M. Howe, and J. W. Richards. 'On the Heat Treatment of Steel Castings,' a paper by C. D. Young, O. D. A. Pease, and C. H. Strand, was presented by Mr. Pease. The discussion was by E. F. Cone and John Howe.

C. M. Weld read by title 'Notes on Iron Ore Deposits near Hongkong, China.' The concluding paper of the morning session was presented by W. S. Potter on 'Manganese Steel, with Special Reference to the Relation of Physical Properties of Microstructure and Critical Ranges.' This was a very long paper with a great number of microphotographs. The presentation lasted until 1:30 p.m., and the audience had dwindled down to 14, including the author, chairman, and the newspapermen. There was no discussion, but the chairman, Mr. Sauveur, complimented the author on the enormous amount of information contained in the paper.

At the afternoon session, J. W. Richards presided. The 'American Steel Rail Situation,' by R. W. Hunt, was read by title in the absence of the author. 'Manganese Steel Rails,' by Sir Robert Hadfield, was read by title, and discussed by W. S. Potter and J. W. Richards. 'Blast-furnace Operation with a Turbo-Blower,' by S. G. Valentine, was the next paper, with discussion by J. E. Johnson, Jr., J. W. Richards, K. Niecker, and L. Waldo. Some of the speakers doubted the correctness of the figures given by the author, as being possibly based on wrong calibrations of instruments. 'Gas Cleaning at Duquesne Blast-furnace' was read by A. N. Diehl. This rather interesting paper elicited considerable discussion which brought out a full account of gas cleaning at the Edgar Thompson works of the Carnegie Steel Co. 'Pig Steel from Ore in Electric Furnaces,' by R. M. Keeney, was read by title. Mr. Richards expressed his great interest in the paper. Heinrich J. Frey's paper, 'On the Utilization of Blast-Furnace and Coke-Oven Gas for Power Purposes,' was an interesting and elaborate one, which resulted in considerable discussion. The paper by C. B. Murray on 'Need of Uniform Methods of Sampling Lake Superior Iron Ore,' was read by title, but gave some extended discussion by Mr. Kelley and Mr. Sweetser, to which Mr. Murray replied.

At the oil and gas meeting there was a large number of papers read by title or in abstract. These included 'Geology and Technology of the California Oilfields,' by Ralph Arnold and V. R. Garfias; 'Chlorides in Oilfield Waters,' by C. W. Washburne; 'Water Intrusion and Methods of Preven-

tion in California Oilfields,' by Franklyn W. Oatman; 'The Age and Manner of Formation of Petroleum Deposits,' by E. T. Dumble; 'The Killing of the Burning Gas Well in the Caddo Oilfield, Louisiana,' by C. D. Keen; 'Is It Feasible to Make Common Carriers of Natural-Gas Transmission Lines?' by Samuel S. Wyer; 'Rock Disturbances Theory of Petroleum Emanations v. Anticlinal or Structural Theory of Petroleum Emanations,' by Eugene Coste; 'The Russian Oilfields,' by A. Adiassevich, presented in abstract by Mr. Coste; and an illustrated address on 'Oil and Gas Sands' by I. N. Knapp. The organic and inorganic theories of the origin of oil were discussed by Mr. Coste, who favors the latter theory, while Mr. von Hofer's paper backed the organic theory.

TORONTO, CANADA

SPECULATION IN STOCKS AND PETERSON LAKE.—NIPISSING'S FUTURE PROFITS.—SCHUMACHER AND LALLY COMPANIES.—IRON ORE ON ISLANDS IN HUDSON BAY.

There has lately been a marked revival of activity in the demand for Cobalt stocks, and a large number of the cheaper issues have changed hands at advancing prices. The most noteworthy feature was the sudden rise in Peterson Lake, which about a week ago advanced from 25c. to 50c. on the news of a discovery of high-grade ore on the former Kerry leasehold, which is now being operated by the Peterson Lake. An old drift was followed from the Keewatin into the conglomerate formation, where two veins, 3 and 4 ft. wide, of high-grade ore were cut. On the strength of the demand created by this find, about 200,000 shares were sold in one day. The price has since dropped considerably, as the result of profit taking by shareholders tired of waiting for dividends. While the lower-priced stocks are looking up, Nipissing has been rather under a cloud and subject to depression, owing to the likelihood that the present dividend rate of 7½% per quarter may be cut. To maintain this rate requires an annual profit of \$1,800,000, and the present production barely reaches that point. The output for 1913 was approximately 4,600,000 oz., which was produced at a cost of 17.39c. per ounce. This year it is estimated that the cost will be at least 18c., while the average price of silver is not likely to exceed 57c. per ounce, so that, allowing that the output is maintained, the profit is calculated at \$1,794,000. As the management is disposed to be conservative and will certainly provide against the possibility of running short of funds for development, a reduction in the dividend rate appears probable in default of important new discoveries of high-grade ore.

The Schumacher, hitherto a private enterprise, which has 160 acres adjoining the Dixon claims and the McIntyre, has been incorporated with an authorized capital of \$2,000,000, and will put its stock on the market. Another new incorporation is the Lally Gold Mines, Ltd., which takes over the Lally mine in Turnbull township, where considerable development has been done and a quantity of ore is on the dump. Machinery is ready for installation. The authorized capital is \$3,000,000.

The Ungava Miners & Traders, Ltd., a Montreal company, has been granted by the Canadian government 30 mining claims on Clarke, Armstrong, and Curran islands in Hudson bay, about five miles from the mainland on the eastern shore of the bay. W. Tees Curran, the manager for the Company, has made several exploring expeditions in that region to search for minerals, and upward of \$50,000 is said to have been spent in work on the islands where extensive iron ore deposits have been found. The iron ore content of the beds on two of the islands, which vary from 7 to 15 ft. in thickness, is estimated at 465,000,000 tons, and the ore is stated to be of fine quality. An expedition will leave Montreal for the islands before long.

PORCUPINE, ONTARIO

HOLLINGER MEETING. — MCINTYRE DEVELOPMENT. — PORCUPINE CROWN DIVIDEND. — CROWN RESERVE MEETING. — MANN MINE SOLD.

The third annual meeting of the Hollinger Gold Mines, Ltd., was held at Montreal on February 2, N. A. Timmins presiding. The past year has been a prosperous one, details of which were given in this journal of February 14. The McIntyre company is developing its lower levels from the Pearl Lake shaft with good results. A vein 8 ft. wide has been cut at the 600-ft. level. This is the deepest working in the camp. The Porcupine Crown company has paid its initial dividend of 3%, and will be put on a 12% per year basis. The annual report shows a profit of \$150,572. The Company has added \$124,048 to the value of its equipment during the year. The president, Mr. Carson, stated that the mill would shortly be treating 180 tons of ore per day.

At the annual meeting of the Crown Reserve, held at Montreal on January 29, Mr. Carson, the president, announced that it was proposed to continue the payment of dividends on the present basis of 2% per month and to explore the bottom of Kerr lake. Development work done during the year was far in excess of any previous year's record, totaling 5345 ft. The production of the year was 1,776,678 oz., and the net value of shipments \$1,040,117. The profits were \$528,287. The Temiskaming is again shipping ore, several short shoots of high-grade ore having recently been cut. The main shaft is being sunk to 800 ft. Negotiations which have been carried on for some time for the purchase of the Mann mine, Gowganda, by an English syndicate headed by Claude Maitland, have been satisfactorily closed, and the purchasers have assumed control. The syndicate includes Sir John Graham of Glasgow and Hudson Bros. of Newcastle, and it is understood that they are preparing to spend a large sum in development. The purchase price is said to be \$500,000.

In connection with new regulations concerning oil in Canada, the Dominion parliament has been requested by the British Government to adopt legislation prohibiting the export of oil in time of war. New regulations have also been promulgated as to the disposal of petroleum and of natural gas rights on Dominion lands, under which the price of leases is fixed at 25c. per acre for the first year and 50c. per acre for each subsequent year, the leases to last for 21 years, and to be renewable for a similar term. The maximum area to be leased to any one person is fixed at 1920 acres, and lessees must have on their property an equipment to the value of \$5000 within one year and begin operations within 15 months. Where several locations are grouped, the equipment need not exceed in value \$10,000.

LUNING, NEVADA

SITUATION, ORE PRODUCTION, AND PROSPECTS OF THE LUNING MINING DISTRICT.—SHIPPER, LUNING GOLD, LUNING-IDAHO, CHAMPION, ALAMEDA, COPPER QUEEN, WAGNER AZURITE, AND ANDERSON MINES.

The Luning district, that portion of Mineral county lying east of Hawthorne and north of Mina, and the adjacent part of Nye county, so named from the fact that Luning is the natural distributing and shipping point for the territory, has long been known to possess remarkable surface copper showings as well as promising prospects for other metals. Until recently development work has been of such a character, and done in such a manner, that no real benefit has accrued therefrom. Within 18 months, systematic development has been started by well financed companies or individuals, and in every case the results obtained have more than justified the operators in their undertakings. During the past year

9759 tons of copper ore was shipped from the district. This ore contained from 3 to 16% copper, 10 to 30 oz. silver per ton, as well as small amounts of gold. A leaching plant is now being constructed by the Wagner-Azurite company, and local operators are awaiting with great interest the results of this undertaking, as the successful operation of such a plant, with its low treatment cost, as compared to the existing freight and smelter rates, will render commercially valuable a large tonnage of ore that cannot under present conditions be worked at a profit. This will mean increased mining activity, and the coming season should witness developments of note in this district. Ancient limestone, cut by monzonite and granitic intrusions and flows, forms the surface in the vicinity of Luning, though different local areas show exposures of porphyritic rocks and later intrusions.

The Shipper Copper Mining Co. owns two claims situated about $3\frac{1}{4}$ miles southeast of Luning. Control of the Company was secured by a group of operators from Spokane and other towns of eastern Washington, in July 1913, and the property financed for development. Traversing the claims in a northeasterly and southwesterly direction are two, and sometimes three, parallel outcrops. These are easily traced for 3000 ft., and show commercial copper ore at intervals throughout their length. They are in dolomite, though a bed of blue limestone may ultimately prove to be the hanging wall of the deposit. An incline shaft has been sunk to the 400-ft. level, giving a vertical depth of 300 ft. below the surface, and several hundred feet of laterals have been driven. This work has demonstrated that the veins cut the limestone beds at a slight angle and that the grade of the ore is improving as depth is attained, though the veins still show evidence of prolonged leaching action. Cross-cuts will soon be driven to determine the width of the mineralized zone, and work on a 3000-ft. adit will be commenced early this summer. This will develop the property 900 ft. below the present workings, and preliminary work has shown that ore of a shipping grade occurs at the point selected to begin work. The Shipper has produced about \$17,000 worth of ore during the past two years.

A reorganization of the Luning Gold Mines Syndicate is complete, it having 13 claims situated about six miles northeast of Luning. Extensive development has been done on the property. Large bodies of ore have been blocked out, of sufficient value to pay a good profit, could it be worked on the property, but not of high enough grade to stand the expense of shipment to Salt Lake. These veins contain gold, silver, and lead. The veins run nearly north and south. About two years ago a cross-vein was discovered, carrying considerable gold and silver, and about \$7000 worth of ore has been shipped since, from above the 50-ft. level. Little work has been done recently, but the Company expects to start work on a larger scale soon and cut the vein with an adit about 400 ft. below the croppings. The adit necessary would be about 450 ft. long. On its completion the Company will be able to make a large production of ore that will pay a handsome profit. Some of the former carload shipments yielded \$50 per ton.

The Luning-Idaho Mining Co. has 13 claims adjoining the property of the Luning Gold Mines Co., and several of those veins enter its property, and sufficient work has been done to prove the continuation of the veins. The claims have a good copper showing, and most of the work has been done on the copper veins or deposits. The deposit is about 250 ft. wide, and appears to have a granite hanging and quartzite foot-wall, and can be traced on the surface for about 3000 ft. The work done consists of several open-cuts, trenches, and shafts, dug to determine the proper place to sink a working shaft. A shaft is being sunk and is down about 30 ft., all in 5 to 12% copper ore. Sulphides are just making their appearance. As soon as roads are completed to ore dumps, shipping will be started. This seems to be a well defined vein,

and should make a large producer with a small expenditure.

The Champion property consists of seven patented claims, and has been developed to a depth of 400 ft. Considerable ore has been shipped in past years, and there are about 2000 tons of commercial ore on the dumps at present.

C. R. Dwight and T. R. Davies have recently undertaken the development of the Alameda property under a lease and bond agreement. The 13 claims comprising this group include the old Lime Point mine that is credited locally with a production of \$800,000. The present operators are developing two veins whose outcrops are traceable on the surface for about 2000 ft. These are apparently fissure veins in limestone, and recent work indicates that the property is one of great merit. Seventy-three tons of copper ore, carrying 8% copper and 4 oz. silver, extracted during development work, was shipped to the smelter last month.

The Copper Queen group, consisting of 64 claims, has recently been bonded by A. C. James and associates. Considerable surface work has been done preparatory to inaugurating an extensive plan of developing the promising surface showings that were uncovered by Fermina Sarrias,

Company is now erecting a plant for the treatment of these ores and expects to be operating within about 30 days. The plant was designed by John D. Fields, and is to have a capacity of 100 tons per day. It is a departure from the usual leaching practice in that the ore is ground fine and leached in a specially designed agitator containing an acid-proof filter. The pulp, after treatment with sulphuric acid, is treated by amalgamation to recover the gold and silver content. The copper is recovered from the solution by iron precipitation, but it is expected that electric power will be obtained in a short time, which will permit the installation of electrical equipment to produce the highest grade of electrolytic copper.

The Anderson mine, situated 4½ miles due east of Luning, was taken over upon a lease and bond by the Mason Valley Mines Co. about a year ago. The Company has worked it continuously since that time, and has shipped 6000 tons of ore with an average copper content of 3% and 1 oz. silver.

MELBOURNE, AUSTRALIA

RESULTS IN 1913.—A GENERAL DECLINE IN STOCKS.—DIVIDENDS PAID.—GREAT COBAR AFFAIRS.

The year 1913 is not one to be looked back to with pleasure by holders of mining stocks. In view of the decline in the price of the chief industrial metals, the drop in the mining shares outside of gold mining is not surprising. The Barrier, Broken Hill, shares show a decided fall. The decline in the value of Broken Hill Proprietary shares amounts to approximately \$2,500,000, or about \$2.50 per share, equal to more than 23% on the price ruling at the beginning of last year. That is not, proportionally, the most serious decline. Setting aside Junction shares, which have declined from \$2 to 60c., equal to a total drop of \$280,000, for reasons not connected with movements in the metal market, the greater percentage decline has been in Block 14, which has dropped almost \$1 on a price of about \$2.75 per share, that is to say, over 36%, equal to a total of \$100,000. Zinc Corporation shares have not moved, and North have appreciated slightly, a little over 3%; but everything else has dropped, the total fall for the 10 important big companies operating in the field being \$6,711,143, making the present value of \$42,886,610. The dividends paid during the year totaled \$7,170,124, or including investment companies dependent upon the success of the mines, about \$8,250,000. The Broken Hill South paid its shareholders nearly \$1,500,000 in dividends, the North Broken Hill, \$1,200,000, and the Proprietary over \$1,000,000; and the Sulphide Corporation, Zinc Corporation, Amalgamated Zinc, the Silverton Tramway Co., and British Broken Hill, all between \$500,000 and \$1,000,000, the three first named being much nearer the larger amount than the smaller. Most of the shares in all the leading companies are held in Great Britain and Europe.

In view of the easing in the price of copper, it is not remarkable that copper shares have followed the lead of the Broken Hill silver-lead companies along the downward path. The principal copper mines are, in Queensland, Mt. Elliott and Hampden; in New South Wales, Great Cobar; and in Tasmania, Mt. Lyell; and all these are materially lower than they were a year ago, though it is only in the case of the last named that the state of the metal market must be held responsible. Among tin shares, the chief market movements have been in those of the Ardlethan field, New South Wales, where an unwarranted boom suffered an ignominious collapse. Gold shares have not been much in favor and have ruled generally lower. Among the companies mentioned above as having experienced a heavy decline in market values is the Great Cobar. The \$25 shares a year ago were as low as \$1.25, and the accounts will probably show loss for the year just ended. The Company has been considerably overcapitalized.

MAP OF NEVADA.

he owner. The ore occurs in the form of carbonates, oxides, silicates and some sulphides, occurring in the garnetized lime, along its contact with the granitic intrusions.

The Wagner Azurite Copper Co. owns 16 claims adjoining the Nevada Champion and Anderson properties, about four miles east of Luning. By a system of open-cuts and shafts, the property has been opened for a length of ¼ mile and a width of 1500 ft., between a monzonite foot and quartzite hanging wall. The orebodies show strong on the surface, giving an average of 2½% copper. The ore carries ¾ oz. of silver to 1% of copper, and also some gold. The working shaft at present is only 100 ft. deep, with cross-cuts at the 50 and 100-ft. levels. With the present development there is apparently 50,000 tons of commercial ore available. The

General Mining News

ALASKA

Dogs are mostly used in Alaska for transport in winter; but Pete Bucholz, of Fairbanks, who has gone to the Beaver district, is trying to use a tame moose for this purpose. This will be the first time that these animals have been employed.

JUNEAU

January gold returns from the mines working on Douglas Island are as follows:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United. |
|------------------------------|--------------------|----------------------|-------------------|
| Development, feet | 34 | 252 | 1377 |
| Stock of broken ore, tons .. | +2899 | -51,846 | -19,924 |
| Stamps working | 120 | 540 | 240 |
| Ore crushed, tons | 19,656 | 69,930 | 37,039 |
| Concentrate saved, tons | 377 | 1445 | 742 |
| Gold by amalgamation | \$20,593 | \$120,576 | \$41,614 |
| Gold by cyanidation | 18,635 | 75,785 | 27,437 |
| Total realizable value | 38,836 | 194,398 | 68,361 |
| Estimated net profit | 8,288 | 114,544 | 13,257 |

There was a loss of \$247 in working the 700-Ft. claim, which produced ore worth \$1.53 per ton. Development in this property, operated by the Alaska United, covered 1236 ft. The work on the 1570, 1750, and 2100-ft. levels consisted of, principally, skip-chute raises and cutting the station and orebins at the central shaft.

RUBY

Mining on the creeks around Ruby is progressing fairly well, according to E. C. Hill, United States commissioner at this centre. Not so many winter dumps will be taken out on Long creek as last winter, but the summer will be busy enough. The Greenstone ground has been bonded by T. J. Coffey and associates to J. Holmgren, Duncan Michie, and Pete Jenson for \$65,000, and great interest is taken in developments. Ruby is dull at present, owing to the number of people going to new fields. About 400 went taking over \$200,000. Some are returning to the district, which produced about \$600,000 last season. This year's output will be higher.

ARIZONA

COCHISE COUNTY

The Calumet & Arizona mine is sending 2200 tons of ore daily to the smelter and stockpile. Transport of ore from the Briggs to the Junction shaft by electric locomotives is about to start. This line will be extended to the Hoatson. A 25-lb. rail is used in the C. & A. underground electric lines. On the 1400-ft. level it is 3300 ft. long, and on to the Hoatson will be another 2200 feet. Installing the pump at 1800 ft. in the Junction is under way, and is a trying job. Prospecting on the 1400-ft. level is promising. Sulphide ore is soon to be extracted from the Pittsburg & Duluth area, entered from the Cole shaft. There is a large tonnage of oxidized ore developed at 900 and 1000 ft. at this shaft.

GILA COUNTY

(Special Correspondence.)—Experiments are still being continued in the old mill of the Old Dominion, with the view to determining the method of concentration best adapted to the ores, but it is anticipated that a definite decision will soon be arrived at, and the remainder of the equipment necessary for the new plant will shortly be ordered. In the mine, ore production and development work are being increased somewhat. Motor haulage is being installed on the 1200-ft. level, and heavy rails are now being laid and the trolley wire strung along the drifts. Two new 3-ton locomotives have been or-

dered for this service. On the 1800-ft. level, the foundation for a Worthington pump has been finished and the pump will soon be working. Excavation for the big pump station on that level will commence immediately, and a drift will be run over to the 'A' shaft. Three furnaces are in blast at the smelter.

Globe, February 21.

(Special Correspondence.)—The U. S. Reclamation Service has the copper wire for transmission of power strung up to the tower at the millsite of the Inspiration. However, this wire has yet to be tightened and the insulators placed before it will be ready for service.

Miami, February 21.

The Gibson mine has been acquired under bond and lease by G. A. Whitford and O. B. Kemp, of Nevada and California for J. R. Davis of San Francisco and B. F. Carney of Berkeley, California. A mill, using a flotation process, of 60 to 80-ton daily capacity, will be erected. The mine, which is in the Pinal mountains, 9 miles west of Miami, and 16 miles from Globe, has produced \$1,600,000 since 1906.

Fine samples of asbestos have been discovered in the Ash Creek district, 35 miles northwest of Globe, by West & Sons.

The property of the London Arizona Consolidated Copper Co., consisting of approximately 2357 acres of mineral lands, is situated in the Banner mining district, in the recognized copper belt of the state. The Globe district lies about 25 miles north; the Hayden plant of the American Smelting & Refining Co. is about 3½ miles from the property, and the district is served by the Phoenix & Eastern railway, a branch of the Southern Pacific. The ores contain copper, with less important quantities of lead and silver. The veins have been proved to 1200 and 1400 ft. The property has been favorably reported on by S. F. Parrish of Los Angeles, Henry Kehoe of Spokane, E. W. Brooks of Los Angeles, W. B. Potter of St. Louis, R. D. O. Johnson of Winkelman, Walter G. Swart of Denver, and Edmund Juessen of San Francisco.

Reserves in the Southwest Miami, according to the superintendent, Mr. Hoar, are 981,000 tons of 1.5% copper ore, and probably 895,000 tons of 1.4% ore. The developed and probable ore is estimated at 4,294,000 tons containing 1.2% copper. Drilling is to be continued with two machines, there being funds for about six months.

A contract has been let to the General Electric Co. for three 6000-kw. turbo-generators for the joint power station of the Inspiration Consolidated and International Smelting & Refining companies. This plant will be between Globe and Miami. C. C. Moore, of Los Angeles, will supply the steel building.

MOHAVE COUNTY

Four shafts and other work has opened good ore in the Arabian Consolidated mines, in the Union Pass district. Sulphide ore has just been reached in the Arizona Southwestern mine, and the shaft is to be sunk within 30 days. Some good copper ore is to be sent to the Copper Queen smelter from J. J. Connolly of Bobtail Basin. The Rainbow Mountain Mining Co.'s property, at Chloride, is opening well, especially at 400 feet. Shipments will be made soon. The ore contains gold, silver, and lead.

PINAL COUNTY

(Special Correspondence.)—The management of the Magma mine states that the company intends to build an aerial tram from Superior to one of three points, Miami, Ray, or a point on the desert to which a spur will be laid from the main line of the Southern Pacific. The final choice of route depends on several conditions, principally what encouragement the officials of Pinal and Gila counties give, and the terms and length of contracts they will be able to secure from the three different smelters involved, namely, the International Smelting & Refining Co.'s plant now building at Miami, the El Paso smelter, and the one at Hayden. The line to Miami would be 15

miles long, that out on the desert would be 10 miles, and the one to Ray would be the longest of the three. The contemplated line's importance is best understood when it is stated that the present rate paid for freight from the Superior district to the railway at Florence is \$10 per ton, and that the cost of delivering it by an aerial tram to Miami, for instance, would be about \$1 per ton. The line will not only carry the Magma's output but will have a considerable revenue for that company in handling of output of the entire Pioneer district, and incoming supplies at only half the present freight rate. Estimates have already been secured from steel companies and the management has practically finished its estimates, although it will not give out the approximate cost of such a line. That to Miami, however, probably would cost somewhere from \$200,000 to \$400,000, according to the size of towers, weight of equipment, and general details of construction.

Superior, February 28.

YAVAPAI COUNTY

In the Silver Cord and Brooks claims, gold-silver-lead ore has been proved to continue for a great length by adits, open-cuts, and cross-cuts. Rich gold-copper ore has been opened in the claims owned by F. Williams and J. Hobbs, two miles from Copper Basin. A deal is pending for 800,000 tons of tailing of the Congress mine. Developments in the Pocahontas mine have been good. Improvements at the Blue Bell mine and Humboldt smelter continue.

CALIFORNIA

Occurrence of graphite has been reported at various times from Calaveras, Fresno, Los Angeles, Mendocino, San Bernardino, Siskiyou, Sonoma, and Tuolumne counties, according to F. McN. Hamilton, of the State Mining Bureau. In 1913, Calaveras county produced 2500 lb. of graphite having a spot value of \$20 per ton. Save a small amount mined in Sonoma county in 1901-2, this is the first commercial yield of the mineral. Prices vary from \$10 to \$200 per ton for impure and high grades respectively.

Deposits of iron ore of varying size and quality are known to exist in 31 of the 58 counties in the state. The production during 1913 amounted to 2343 short tons valued at \$4485, as compared with the 1912 output of 2508 tons with a spot value of \$1 per ton.

AMADOR COUNTY

Work on foundations for the new Plymouth mill is still under way, and concrete is being poured. Several contracts have been let for the plant, among which are the stamps and boxes by D. D. Demarest Co., two 8 ft. diameter by 22-in. cylinder Hardinge pebble mills by the Hardinge Conical Mill Co.; and Isbell vanners by the Isbell Mining Machinery Company.

BUTTE COUNTY

The Natomas Consolidated of California, which operates dredges at Thermalito, near Oroville, is taking steps to exterminate the mosquito there. Charles Thurman has men engaged in pouring crude oil on the surface of the abandoned ponds to prevent the mosquitoes from breeding.

Two dredges of the Oroville Dredging Co. recovered \$5699 during the last week of January.

ELDORADO COUNTY

W. H. Friendhoff of the U. S. Geological Survey, and E. L. Scott of the Forest Service, have been examining mineral claims on the Georgetown divide. A field deputy from the division office at San Francisco, with E. E. Jones of the Forest Service, is inspecting the forest reserve in the eastern part of Eldorado and the northern part of Amador counties.

INYO COUNTY

The annual report of the Tecopa Consolidated company, operating at Resting Springs, shows that the Gunsite mine

produced 10,000 tons of ore worth \$128,000. Of this, \$40,000 was paid for freight. Net profits from this mine were \$52,000. The Noon Day produced 1000 tons yielding \$1499 profit. Mining cost from \$1.66 to \$3.62 per ton. The monthly payroll is \$4000 at present. A plant of 30 to 50-ton capacity, costing about \$25,000, will probably be built. This would concentrate low-grade ores. The mines are opening satisfactorily. N. L. Graves is president.

NEVADA COUNTY

(Special Correspondence.)—A hoist with a capacity of 4 to 5 tons, from a depth of 7500 ft. on an incline of 30°, is to be installed at the Empire mines, Grass Valley. A 60-stamp mill will be erected during the current year; but the plans are not yet complete.

Grass Valley, February 25.

On February 26, masked and armed bandits held up the night shift in the Central cyanide plant of the North Star Mines and stole from 50 to 100 lb. of gold precipitate worth

VIEW OF GRASS VALLEY FROM EMPIRE MINE.

from \$2000 to \$3000. The robbers cut the telephone wires from the plant, so that an early alarm could not be given. Evidently they knew of the routine work of the mill, as a clean-up was to have been made on the day of the robbery. A. B. Foote is superintendent of the North Star Mines.

The men who robbed the North Star Mines cyanide plant have since been captured.

PLACER COUNTY

Over 400 acres of land in the Gold Hill district, in Auburn ravine, has been purchased by L. Gardella of Oroville, who will drill it and erect a dredge during the current year.

SISKIYOU COUNTY

The Butte Dredging Co. is sending lumber and material to Greenhorn gulch, near Yreka, and will construct a dredge to cost \$150,000. In charge of operations are L. T. Parkes of San Francisco, B. F. Masten and E. W. Stebbins of Oakland.

TRINITY COUNTY

Ten to twelve inches of specimen ore and four feet of low-grade material has been opened at a depth of 135 ft. in the Democrat No. 1 mine, two miles from Weaverville. E. E. Harrigan is owner of the property.

TUOLUMNE COUNTY

The O. K. group of claims, joining the Tarantula on the north, have been bonded to Los Angeles people. Several men have started work at the property. An experimental cyanide plant is being installed near the Harvard mine, by W. H. Staver, formerly of the Liberty Bell mine, Colorado. He will show that concentrate can be more economically treated locally than by shipping to smelters. O. E. Prestegard is assisting Mr. Staver.

COLORADO

TELLER COUNTY (CRIPPLE CREEK)

The annual report of the Acacia Gold Mining Co. shows that, with the exception of the south Burns shaft, the property was worked by lessees. Fair ore was opened on No. 9 level at this shaft. Total receipts were \$10,303, including \$2032 for royalties. There was a deficit of \$4173 for the year. Cash on hand amounts to \$3358. R. MacKenzie is manager. No annual meeting of the Jennie Sample Consolidated Mining Co. is to be held; but the report shows that lessees mined 1440 tons of ore yielding \$27,571, producing \$4177 net royalty for the Company. Cash on hand is \$2341, with no debts. The Beacon Hill property of the El Paso Consolidated is expected to produce 3500 tons of \$30 ore in February. A dividend of 10c. per share and 490,000 shares has been paid. Henry Martin, a sub-lessee at the W. P. H. mine on Ironclad hill, has opened 12 ft. of rich ore between the 200 and 300-ft. levels. This is supposed to be the faulted Harrison and Sevier shoot, which produced \$315,000 in 1904.

Estimates of the February gold output of the district show 71,293 tons treated, worth \$988,578. Dividends totaled \$145,000.

IDAHO

BLAINE COUNTY

There will be considerable activity in the Wood River district in the spring and summer, especially at the Plughoff and Reed at Glendale, Minnie Moore, Queen of the Hills and Queen Extension, Croesus, Clipper, Hidden Treasure, Donahue and Warning, Red Elephant, Bullion, Nay Aug, Boston-Idaho, Boulder, Million, Independence, Noonday, North Star, and others.

SHOSHONE COUNTY

On March 4 the Bunker Hill & Sullivan company paid dividend No. 198, amounting to \$81,750. Developments in the Wisconsin mine, 2½ miles northeast of Kellogg, are extremely good, and if they continue, a mill will be erected later on. Louis Bolduc is manager.

MICHIGAN

HOUGHTON COUNTY

Copper shipped over the South Shore railway during the first three weeks of February shows an increase of about 720,000 lb. over the same period of 1913. The old Allouez conglomerate lode has been opened by a cross-cut in the Franklin mine, at a depth of 3200 ft., and contains more copper than in the upper levels. On March 20, the Calumet & Hecla Mining Co. will pay a dividend of \$5 per share, amounting to \$500,000. The total paid to date amounts to \$129,400,000. The annual report of the Victoria Mining Co. shows the following:

| | |
|---------------------------------|-----------|
| Development, feet | 7,428 |
| 'Rock' hoisted, tons | 159,565 |
| Sorted out (14%), tons | 22,402 |
| Copper production, pounds | 1,428,693 |
| Revenue from all sources | \$228,335 |
| Loss on operations | 7,494 |

Labor troubles caused the loss, but development and output were ahead of the previous year. Seven Ingersoll water Leyner drills, operated by one man each, were started during the latter part of the year 1913.

NEVADA

According to A. F. Gegan, Nevada representative of the Hercules Powder Co., and who covers the districts west of Palisade, mining generally in the state is sound and steadily increasing. The consumption of dynamite is considerably heavier than a year ago. Goldfield is more active; Tonopah is very busy; Manhattan is quieter, but will improve soon; Round Mountain is developing well; Battle Mountain, Copper Cañon, and Kimberley are promising; Buckhorn has its new mill work-

ing; Yerington copper is temporarily quieter; more miners are being employed at Luning, which is described in the 'Special Correspondence' portion of this journal; and the Pioneer and Good Springs districts are improving.

CHURCHILL COUNTY

The Nevada Hills mill produced \$36,304 from 4415 tons of ore in January with a profit of \$6638. The loss in residue was \$1.41 per ton. Cash on hand and in banks is \$51,682, and total resources \$194,003, with no liabilities. All litigation is finished at a cost of \$2500. An old ore dump was bought for \$5220 and is being milled at a profit.

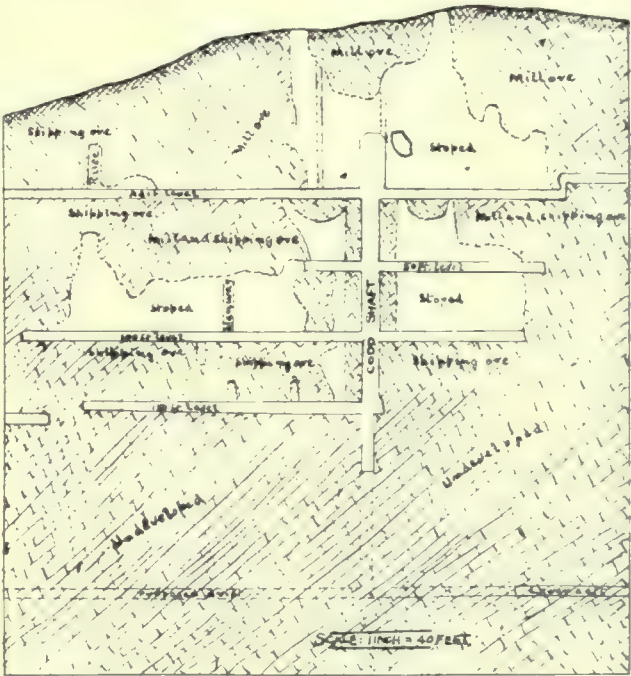

ESMERALDA COUNTY

At a meeting of the board of directors of the Goldfield Consolidated Mines Co., held at Reno on February 26, a dividend of 30c. per share was declared, payable April 30 to stockholders who are of record on March 31. This will amount to \$1,067,744, making a total of \$27,398,215 to date, equal to \$7.70 per share.

The February yield of the Goldfield Consolidated was \$344,000, from 26,774 tons of ore, with a net profit of \$179,000.

HUMBOLDT COUNTY

The Rochester Hills Mining Co. has a capital of \$1,000,000 shares of \$1 each, and operates a property producing silver and gold ores at Rochester. The annual report deals with the year 1913. A. A. Codd is president, and H. C. Zulch, mine superintendent. The former's report states that this is the Company's first year and it has been entirely satisfactory. The question of ore and supplies transport to and from the district mines to Oreana, on the Southern Pacific, was solved

VERTICAL SECTION THROUGH VEIN, LOOKING WEST
ROCHESTER HILLS MINING COMPANY.

by constructing a narrow-gage railway 4½, and a wagon-road 9 miles long. The equipment consists of a Baldwin oil-burning steam locomotive, a 60-hp. gasoline locomotive, two flat cars, 10 ore-cars, ore-bins of 500-ton capacity, depot, and dwellings. The rails are 35 and 62 lb. per yard. This line has been of great benefit to the Rochester district. With a power-plant consisting of one 25-hp. Fairbanks-Morse oil engine, a 240-cu. ft. per minute duplex air-compressor, six machine drills, Westinghouse generator of 50-light capacity, and a 6-hp. Fairbanks-Morse hoist, as much as 250 tons of ore has been mined in a day. The mine is now 225 ft. below the adit level, and a larger equipment is to be installed. This consists of a 75-kva. generator, a 50-hp. motor and appa-

ratus, a 9-drill, 2-stage air-compressor, drill sharpener, and an electric hoist. During 1913 the sum of \$43,959 was spent on equipment generally. The mine was developed by an adit level, from which was sunk a 2-compartment shaft and manway. The shaft is 165 ft. below the adit. Levels have been driven every 50 ft. A rich vein, known as the East, about 300 ft. east of the present vein, is to be developed at an early date.

Herman C. Zulch reported that development covered 2316 ft. The accompanying section of the mine shows the ore which is shipped at a profit, and the mill ore, which is from 4 to 14 ft. wide, worth \$12 to \$16 per ton, and amounting to 25,000 tons. Late in January 1914 a shoot was opened on the hanging wall of the 150-ft. level, assaying \$5 to \$8 gold and \$40 to \$87 silver per ton. Financial results were as follows:

| | |
|--|-----------|
| Ore shipped to smelter, short tons..... | 9,167 |
| Gross value | \$175,762 |
| Smelter charges, equal to \$6.20 per ton..... | 72,464 |
| Transport, equal to \$4.40 per ton..... | 40,684 |
| Net return | 62,613 |
| Revenue in 1913 from ore and stock sales, etc..... | 187,873 |
| Expenditure on all work | 181,855 |
| Cash on hand | 6,018 |

NYE COUNTY

Bullion taxes paid in the county during the September quarter of 1913 amounted to \$37,157. Of this the Belmont company at Tonopah contributed \$27,650, part of which was due from 1912, and the first and second quarters of 1913. The Clifford-Nay mine shipped 4930 lb. of ore worth \$2492 per ton during the third quarter. On April 1, the Belmont company will pay 25c. per share, equal to \$375,000. The shaft vein was opened last week on No. 13 level, showing 3 ft. of good ore. The West End shaft is to be sunk from 800 to 1000 ft. The new hoist recently raised 1550 tons with a 2-ton skip in 24 hours, costing 1.7c. per ton, about half the cost with the old engine. At 698 ft. in the Montana, the Macdonald vein is 12 to 15 ft. wide, of which 4 ft. is good mill ore. To permit of a survey being made of the disputed ground, the Jim Butler and West End companies will suspend mining in the Eureka claim of the former until March 10. Probably there will be no litigation over the matter.

SOUTH DAKOTA

LAWRENCE COUNTY

Eastern people have acquired an option on the Far West and other claims in the Carbonate district. Water caused a suspension of work years ago. The Titanic company holds leases and options on several well known claims south of the Far West, and is doing a considerable amount of prospecting. The Oro Hondo mine, situated about a mile from Lead, and adjoining the Homestake on the south, is to be reworked by John T. Milliken, of Cripple Creek, Colorado, under the management of Joseph E. Carr. The shaft is 1950 ft. deep and almost full of water. This will be bailed out and the shaft sunk another 1000 feet.

POTTER COUNTY

After drilling over 2000 ft. and spending from \$25,000 to \$30,000 at Gettysburg, the Fox Oil Co. is drawing the inner casing of the well. It is said that the well is not deep enough to cut the oil strata and suit. drilling machinery was not used.

UTAH

JOAB COUNTY

The Gemini mine, according to J. H. McChrystal, superintendent, produced \$500,000 worth about 20,000 tons of ore in 1912. Of this, nearly \$1,000,000 was from lessees' ore. The present output of the mine is 1800 tons per month. Two hundred tons of 7 to 8% copper ore is being shipped monthly from

the Iron Blossom. Development at 1900 ft. is encouraging, but work has been stopped on levels between this and 700 ft. The annual report of the Eagle & Blue Bell Mining Co. shows that ore shipments were worth \$515,324, containing 7514 oz. gold, 417,279 oz. silver, 4,639,073 lb. lead, and 157,596 lb. copper, all increases on 1912. Development covered 3872 ft., at a cost of \$9.13 per foot. Net earnings were \$147,198. From 8 to 18 in. of silver-gold-copper ore is being opened on the lowest level of the United Tintic mine.

SALT LAKE COUNTY

Larger crushers are to be installed at the Lark mill of the Ohio Copper Co. The three units of the plant have a capacity of 500 tons each per day; but with the changes to be made this will be increased to 1000 tons each. Net earnings of the Utah-Apex Mining Co. for the last quarter of 1913 were \$26,145, compared with \$48,752 in the third term. This decrease was due to most of the mine being sealed in order to try to capture a bandit who was hiding there, bad weather preventing ore and concentrate shipments and a drop in the price of lead. Development work has been excellent. By April 1 the mill will be treating 350 tons of ore per day. Twenty tons daily of lead carbonate ore is being mined by Wade and Tibby, lessees on the Columbus Consolidated portion of the Wasatch Mines Co.'s property at Alta. The railroad from the smelters to Wasatch has reduced transport charge from \$2.05 to \$1.75 per ton.

SUMMIT COUNTY

At the Snake Creek tunnel the advance is 8½ ft. per shift. The flow of water is 2000 gal. per minute, but as it is warm the men are not inconvenienced thereby. The face is at present 1200 ft. below the surface. Excellent reports come from the Silver King Consolidated, especially from the 1550-ft. level. Twenty-five men are working at 800 and 1200 ft. in the old Daly mine, and high-grade ore is being marketed. From the American Flag, \$46 to \$50 ore has been sent to Salt Lake City. This Company has bought the Grasselli zinc plant at Park City, which will be overhauled and the Holt process installed. The snowfall at Park City in January was 64.2 in., and the greatest depth in the mountains was 120 in. near Park City.

WASHINGTON

PIERCE COUNTY

Governor Lister has ordered an investigation of the strike of 400 laborers at the American Smelting & Refining Co.'s smelter at Ruston, a town adjoining Tacoma, according to advices received at Central Labor Union headquarters. The Industrial Workers of the World and Western Federation of Miners have been interfering as usual. A shipment of 250 tons of ore from Cordova, Alaska, containing 65% copper and 18 oz. silver per ton, has been received at the smelter during the past week.

CANADA

BRITISH COLUMBIA

The provincial legislature is alive to the value of radium, and has taken out of the ordinary mineral classification all ores containing this mineral. A reward of \$5000 is offered to anyone discovering such ores, the government reserving to itself 50% of the value of the discoveries.

ONTARIO

All records for silver shipments were broken on February 24, when the Nipissing sent 381 tons, containing 452,336 oz., worth \$260,681, to England. At the Temiskaming mine, at Cobalt, the shaft is down 710 ft. Below the Keewatin, in the diabase, a new series of veins is being opened. Eighteen drills are working. The mill is treating 100 tons of ore per day. During January the Hudson Bay mine produced 1972 tons of ore yielding 56,983 oz. silver, with 89% recovery. The tailing averaged 2.8 oz. per ton.

Decisions Relating to Mining

COAL LAND—PURCHASE PRICE

Where a coal land applicant filed a proper application to purchase, complied with the regulations of the Department as to publication of notice, etc., and paid the price of the land as determined by conditions then existent as to distance from a completed railroad, he is entitled to purchase at that price notwithstanding the subsequent completion, prior to allowance of entry, of a railroad within fifteen miles of the tract.

MINERALS BY ADVERSE POSSESSION AGAIN

The Supreme Court of Alabama (*Black Warrior Coal Co. v. West*, 54 Southern, 200), by a four to three decision, held that Milly West had no interest in the minerals in controversy.

Milly urged that her ancestor owned a piece of land upon which one Garner entered adversely and after the statutory period acquired title. Before the statute of limitation had run, Garner conveyed to the predecessor of the coal company all the minerals in the land. Garner maintained his possession. There was no actual separate possession of the minerals. She contended that Garner's deed operated a severance of agricultural from mineral rights, created two separate estates, was an abandonment of the possession of the minerals, and, as the grantee failed to take possession of the minerals, her ancestor's title to minerals was unaffected by adverse possession, which confessedly ripened as to the surface.

The prevailing opinion appears to be logical. Why three judges should dissent is not clear. May we surmise an innate aversion to title by adverse possession (characterized by a Western court as "title by larceny")?

The West case controlled four judges of the same court to deny a right which seems rather to be fortified by it (*Moore v. Empire Land Co.*, 61 Southern, 940; opinion by Anderson J., who dissented in the West case). No opinion is expressed by the other three members of the court, two of whom also dissented in the West case.

In the Moore case a remote grantor of Kay while endeavoring to acquire title by possession, conveyed surface to the predecessor of a land company, and under that deed continuous possession had been maintained with no one in actual possession of the minerals. The court holds that when Kay conveyed the surface apart from minerals, this as a severance, was a mere legal fiction, and in absence of actual possession of minerals did not operate to sever possession of minerals from possession of surface. The court states that "in the absence of a physical severance, the possession of the surface, and the holder of the surface, if the grantor of the mineral right, or if the holder of the surface was the grantee of the surface right, then he held the possession of the mineral right for the benefit of his grantor of the surface right, but who reserved the mineral right."

This appeals to us as a correct statement of principles though the court adopts it with reluctance because announced by a majority only in the West case; nevertheless the court concludes that the land company has title to the minerals by adverse possession. Can it be that one who holds "possession of the mineral right for the benefit of his grantor of the surface right, but who reserved the mineral right" can thus acquire his grantor's reserved mineral right? Wherein is the benefit to the grantor? Can one hold under a deed at the same time that he claims adversely to it?

A possible solution of the apparent inconsistency is that some possessor held under a deed that ignored the mineral reservation and purported to convey full title; but this would require consideration of other principles, and no such condition is revealed by the report of the case.

Personal

F. H. MORLEY is at Pasadena.

H. H. WEBB is in San Francisco.

DORSEY HAGER has been in San Francisco.

EDWIN HIGGINS was in San Francisco Monday.

C. C. BROADWATER has returned from New York.

H. C. HOOVER has left for New York and London.

REEVES DAVIS, of Happy Camp, is in San Francisco.

J. D. HUBBARD is at Chico, Butte county, California.

CHARLES BUTTERS was expected in San Francisco today.

F. C. ALSDORF, of San Francisco, is in Arizona examining mines.

MALCOLM MACLAREN is returning to London from Kalgoorlie by way of India.

GELASIO CAETANI was at the Plymouth mine, Amador county, California, this week.

HARRY G. HANN is drilling alluvial ground for the Lenskoi Gold Mining Company.

W. H. WEED has been in Butte examining the property of the Butte-Duluth Mining Company.

STANLEY HARROLD, who has been visiting California, will return to Venezuela the last of the month.

P. F. HARE, manager of the Pierce Company, Ltd., dredge at Pierce, Idaho, is in London. He will examine placers in Peru.

FERDINAND MCCANN has gone to the Philippines to take charge of the cyanide plant of the Keystone M. Co., at Aroroy, Masbate.

WALTER W. BRADLEY and FRED L. LOWELL, of the California State Mining Bureau, are examining mining districts in Tuolumne county.

HOWLAND BANCROFT has gone to New York, and expects to sail for Peru today. He will return to Denver at the beginning of June.

MORTON WEBBER, who has been in California, has gone to Salt Lake City and Butte, from which latter place he will return to New York.

F. McN. HAMILTON and ERROL MACBOYLE, of the California State Mining Bureau, have just returned from a tour of the Mother Lode counties.

ROBERT S. TAYLOR, and EDWARD RECTOR are in San Francisco for the Deister Concentrator Co. in connection with the Mine & Smelter Supply Co. litigation.

W. H. STAYER, assisted by O. E. PRESTEGARD, is installing a small experiment cyanide plant near the Harvard mine, Sonora, Tuolumne county, California.

The Montana section of the AMERICAN INSTITUTE OF MINING ENGINEERS held its annual meeting at Butte on February 6, over 50 members being present. The old officers were re-elected. E. P. Mathewson is chairman; Frank M. Smith, vice-chairman; and D. C. Bard, secretary. The above, with J. L. Bruce and Oscar Rohn, constitute the executive committee. After the business meeting the following papers were read and discussed: 'The Drumlunnon Mine,' by C. W. Goodale; 'Economy and Efficiency of Reverberatory Smelting,' by C. D. Demond; and 'The Labor Crisis in Chile,' by Bancroft Gore.

DURING the period October 1 to November 30 there were 7251 men employed at the Lena Goldfields, Siberia, and 102,074 cu. yd. of gravel was mined. Only 10,161 cu. yd., averaging \$8.46 per yard, was washed on account of the winter season.

New York Metal Market Review

In February there was a continuance of heavy copper exports, but a falling off in foreign buying toward the end of the month, which, with a lessened domestic demand, caused a decline in prices. There were heavy sales of lead, mostly at low prices, and American metal was exported to London. In spelter there was good buying in keeping with the greater activity of the sheet mills, but it did not last long. Antimony presented little of interest. There were some fairly good movements in tin, some of which were largely due to manipulation to which there was a reaction and this metal's reputation for violent fluctuation was maintained. Aluminum varied but little in price, for the reason that foreign metal exercised a steadying influence. In nearly all metals the early days of the month saw advances, after which a steady decline set in.

COPPER

Exports of copper in January and February were maintained and in the former month reached the big total of 35,566 tons. Following heavy buying, both foreign and domestic, in the last few days of January, electrolytic stiffened and advanced to about 14.75c. cash, New York, which was quoted when February opened. Prior to the movement referred to the demand from abroad had been much the heaviest, but in early February domestic consumers took the lead. In the face of the advance came a puzzle for the trade in that the American Brass Co. reduced its prices for brass and copper products $\frac{1}{4}$ c. per pound. Various theories were advanced for this step, one being that the Company had bought enough copper for its needs at a low price and was willing to take a proportionate profit, while another was that it did not concede the justification for the advance in price and had decided to take a hand in the game and show its disapproval. A second flurry of buying was a good one, though somewhat spotty, quotations varying from 14.62 $\frac{1}{2}$ to 14.70c. cash, New York, with Europe again figuring in a majority of the sales. After the issuance on February 9, of the Copper Producers' statement for January, which was favorable in that it showed a decrease in stock of 4,142,182 lb. and that domestic deliveries had increased over 26,000,000 lb. over those of December, though still short 20,000,000 lb. of normal, there was some moderate buying of electrolytic, and the market settled at about 14.62 $\frac{1}{2}$ c. cash, New York, where it stood until February 21, when it dropped to 14.50c. cash, New York, a price made by second hands. Toward the middle of February it became known that the demand for brass and copper products had eased off again and that some of the Naugatuck valley mills had again reduced their working hours. Toward the end of the month the market was quiet, although foreign deliveries were keeping up at a good pace. Throughout most of the month the producers were holding ostensibly to their 'peg' price of 14.87 $\frac{1}{2}$ c. delivered, cash 30 days, or 14.75c. cash, New York; but, as already indicated, the metal was to be had at lower figures, and toward the end of the month there was a break in the peg price, and at least one producer had made sales on a basis of 14.62 $\frac{1}{2}$ c. cash, New York. Second hands would take 14.59c. or less. Lake was nominally quoted at 15c. throughout February, though sales of choice brands were made at 15.12 $\frac{1}{2}$ c. cash, New York, and 15.25c. cash, New York. Lake was scarce and the producers were picking their customers. Copper exports up to and including February 26 were 26,140 tons. The Waterbury average for January was 14.75c. per pound.

LEAD

At the beginning of February the American Smelting & Refining Co. advanced its price 5 points to 4.15c. New York, while the St. Louis quotation moved to 4.05c. Demand was fair when the advance was made, but it eased off shortly after, and with more definite rumors of government action against

the large interest, a declining tendency in London, and quiet in the domestic market, it became apparent that lower prices were to be expected. These expectations were realized on February 11, when the New York price was made 4c., a drop which was more than the trade looked for, despite the softness which had prevailed. At the new price business was induced, but many independent sellers withdrew from the market rather than meet the low price. Later in the month they offered to take business again, but consumers evidently had filled up and there was little doing. The St. Louis price had dropped to 3.87 $\frac{1}{2}$ c. and remained there from February 11 to near the close of the month. When the low prices were established there came about what had long been expected, the exportation of American lead to London. It was done very quietly, and while the fact was confirmed, the amount shipped could not be ascertained. It was regarded as natural that lead should go abroad in view of the narrow margin between New York and London prices. The former, of course, were shaded in what transactions there were. One reason for sending lead abroad was the accumulation of a surplus here. Still more exports are expected.

SPELTER

Starting at around 5.40c. New York, and 5.25c. St. Louis, spelter advanced and in the second week of February reached 5.45 to 5.50c. New York, the higher prices being predicated on a much better demand from the sheet mills, which accompanied the better trend in iron and steel generally. Toward the third quarter of the month the demand subsided and quotations declined to 5.35 to 5.40c. New York, with St. Louis 15 points lower. On the decline the West was pressing for business, but not much was stirring.

ANTIMONY

In late January and early February there were fair quantities of antimony taken, after which the demand eased off and there was little of interest in the metal in the remainder of the month. Quotations for Hallett's were uniform at 7 to 7.25c. Cookson's declined a few points, 7.20 to 7.25c. being quoted February 26. Chinese and Hungarian brands showed weakness also, being quoted at 5.87 $\frac{1}{2}$ to 6.12 $\frac{1}{2}$ cents.

PIG TIN

Although tin touched 41c. early in February, its general course was downward and the quotation for prompt on February 25 was 38.12 $\frac{1}{2}$ c. The month's buying was in fits and starts and at times there was fairly heavy buying. February 3, for instance, probably 300 tons was taken in deliveries that ran from spot to June, both dealers and consumers taking the metal. February 4, between 500 tons and 700 tons was sold at 41 to 41.25c., dealers taking many tons in an effort to hold the market up. Thereafter dullness ensued and it was seen that a decline was inevitable. The manipulation caused lack of confidence on the part of buyers, especially those who had bought when the higher prices prevailed. February 18 there was a slight turn from the downward trend and about 200 tons was taken at prices that ranged between 39.25 and 39.40c. Immediately thereafter dullness was in full force again and there were more sellers than buyers and the former were depressing the market to make business. The only buying in the week ended February 25 was of a hand-to-mouth character. The course of prices in London is indicated by the fact that quotations on February 11 were £185 5s. for spot and £186 7s.6d. for futures, while on February 25 there were £173 10s. for spot and £175 10s. for futures. Deliveries into consumption in January reached the excellent total of 3600 tons, as compared with 2700 tons in the same month of 1913. The total visible supply January 31, 1914, was 14,559 tons, which was 888 tons above that of January 31, 1913. On February 26 the arrivals of the month totaled 3020 tons and there was afloat on that day 2970 tons. February deliveries into consumption are estimated as between 2800 to 3000 tons.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, March 5.

| | |
|---------------------|-----------------|
| Antimony | 9 — 9 3/4 c |
| Electrolytic copper | 15 1/2—15 3/4 c |
| Pig lead | 4.25—5.20 c |
| Quicksilver (flask) | \$39.00 |
| Tin | 42 1/2—44 c |
| Spelter | 6 1/2—6 3/4 c |

Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound.

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, March 5.—Electrolytic copper is still weak, declining from 14.25 to 14.15c. per pound. Exports from the United States in February totaled 34,384 tons, against 26,767 tons a year ago. The Miami February output was 3,393,400 lb. Lead is steady at 4c. and spelter is easier at 5.15c. per pound. Tin is quiet at 37.87 to 38.12c. and antimony is dull. In London, copper is £64 2s.6d. for spot and £64 12s.6d. for futures, prices unchanged. Lead is £19 17s.6d., off 2s.6d. Gold bars worth \$2,000,000 have been engaged for shipment to Paris from New York, making \$16,000,000 for the present movement.

SILVER

Consumption of foreign copper in Germany in 1913 was 221,350 tons, according to L. Vogelstein & Co. The total in 1912 was 195,917 tons. Of the past year's imports, 94,638 tons came from the United States.

According to the Department of Commerce, imports of copper and manufactures thereof for December 1913 amounted to \$3,442,810, compared with \$4,609,063 for December 1912. For the year ended with December 1913 the total was \$44,479,568, compared with \$44,315,525 for the year ended December 1912. The exports of copper and manufactures thereof for December 1913 were \$12,666,621, compared with \$11,480,000 for December 1912. For the calendar year of 1913, exports were \$144,909,117, compared with \$126,770,167 in 1912.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at

which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

At the beginning of March 1914 neither zinc nor lead at Joplin is selling as high as they did at the corresponding period of 1913; but the outlook for better prices is fairly good. At this time last year offerings were declining, and many mines which were able to operate at the higher prices that had prevailed were beginning to shut down. Zinc sulphide ores of 60% metallic zinc now sell for \$41 to \$44, basis, with premium grades selling up to \$47, these figures representing an advance of about \$1 per ton over prices that prevailed one month ago. Spelter at East St. Louis has been holding fairly firm at \$5.25 to \$5.35 per 100 lb. For the corresponding week of 1913, zinc sulphides brought \$45 to \$48, basis, with premium grades selling up to \$51 per ton. Calamine is in good demand at \$21 to \$23 per ton, basis of 40% metallic zinc, with premium grades bringing up to \$27. In the corresponding week of 1913 calamine brought \$24 to \$26, basis, with premium grades bringing as high as \$33. Lead ore remains unchanged at \$50 per ton, basis of 80% metallic lead, with premium grades bringing as high as \$4 in excess of this figure. Pig lead, at East St. Louis, is easier at \$3.90. In the corresponding week of 1913 lead ore brought \$53.50, basis, with pig lead quoted firm at \$4.20. The entire district is now producing about 4300 tons of zinc sulphide per week, the average of which will be about 58% metallic zinc, while much of it carries sufficient iron to warrant penalizing. The calamine output is about 400 tons per week which will average nearly 40%, while the lead ore output is about 800 tons which will average almost 80 per cent.

ZINC

Zinc is quoted as spelter, standard Western brands, St. Louis delivery, in cents per pound.

Company Reports

BARNES-KING DEVELOPMENT COMPANY

This Company operates at Kendall, Fergus county, Montana, and the profit and loss account from August 27, 1912, to December 31, 1913, shows the following: Gross earnings, \$414,594; expenses, \$274,889; balance, \$139,705; other income, \$7910; total income, \$147,615; less extraordinary expenses, \$17,709; leaving a net profit of \$129,906.

NEVADA HILLS MINING COMPANY

This Company operates a mine and treatment plant at Fairview, Churchill county, Nevada, the area being 107.5 acres, and the report covers the past year. The report of E. A. Julian, general manager, and Fred J. Siebert, consulting engineer, contains the following information: Development covered, 6243 ft., including 903 ft. of core-drilling, the total to date being 35,660 ft. The Webber shaft is now down to 854 ft., timbered with 10 by 10-in. Oregon pine. Through

prospecting along the Nevada Hills vein and its branches, on the east and west sides of the Big fault, it appears that the limits of the vein have been defined. On the west side of this fault the Eagle vein was opened with encouraging results. On the east side this vein was cut on the 650-ft. level, and opened for 160 ft. in unprofitable ore. Thirty feet above the level good ore was cut. Drilling has cut the Eagle vein at 800 ft., where the width and gold content is better than above. Reserves of ore should supply the mill for another year. The mine produced 41,919 tons of ore averaging \$13.85 per ton, as follows: Nevada Hills vein east of Big fault, 14,538 tons, worth \$18.26 per ton; west of Big fault, 11,793 tons, worth \$12.47; and the Eagle vein, 15,588 tons of \$10.78 ore; the total value being \$580,468. The cost of mining was \$3.80 per ton of ore produced, or \$2.62 per ton of ore and waste produced. The stamp-mill and cyanide plant yielded gold worth \$510,413, with an average recovery of 88.4%, at a cost of \$2.839 per ton. The total expenditure, including development, mining, milling, marketing bullion and concentrate, general, and construction, was \$333,448, leaving a net profit of \$176,966. The Company's resources amount to \$186,802, with no liabilities, consisting of accounts and bills receivable, \$50,763; cash, \$60,618; supplies, \$43,602; concentrate and bullion in transit, \$11,819; and gold in solution, \$20,000.

MOUNT MORGAN GOLD MINING COMPANY, LTD.

The great gold and copper mine operated by this Company is situated in Queensland, Australia, and the report covers the half-year ended November 30, 1913. The general manager, B. Magnus, states that in order that the mine may be in a position to supply the necessary concentrating ore during the coming year, an undue proportion of preparatory work had to be undertaken during the term. This entailed close to 1700 ft. of driving and sinking, against 208 ft. in the previous period, and has naturally absorbed a great number of miners. In the near future an extra 500 tons of ore per day for the concentrator will be required, and the Company is trying to get the necessary number of miners required to produce this, but finds great difficulty in doing so, owing to the extreme scarcity of such labor throughout the Commonwealth and New Zealand. The average daily ore extraction during the six months was 840 tons. The material mined was as follows: copper ore, 117,108; sundry ores, 12,209; waste, 21,680; and filling sent underground, 46,646 tons. Ore reserves amount to 1,285,000 tons of high grade, 1,960,000 tons of low grade, and probably another 3,000,000 tons of concentrating ore.

At the Many Peaks pyrite mine 35,769 tons of ore was mined. The usual work was done at the Marmor limestone quarries. At the coal areas, several thousand feet of diamond-drilling has been done, proving large seams of good coal, so it has been decided to open one of the properties. The smelter handled 152,016 tons of mixed ores, yielding 4354 long tons of copper and 54,992 oz. gold. The revenue was \$496,936, and profit \$172,846. Adding \$46,591 from the previous year, the balance was \$219,437, out of which \$27,883 was written off for maintenance, equipment, coal prospecting, and experimental work; \$24,707 for depreciation; \$100,000 for dividends, and \$66,847 carried forward. The reserve, contingent, insurance fund, and undivided profit total £302,233. Experiments with concentration are still under way, and the Minerals Separation recoveries corroborate those of the Company's metallurgists. Four new boilers were erected, others are being installed, while three turbo-blowers and two air-compressors were erected. Contractors for the new smelter building are considerably behind time. A Dwight-Lloyd sintering plant is to be installed for the flue-dust. A. A. Boyd is mine superintendent, and J. W. Moule reduction works superintendent.

Recent Patents

1,072,373.—PROCESS OF PRODUCING CYANOGEN COMPOUNDS AND THE LIKE. Charles E. Acker, Ossining, N. Y., assignor to The Nitrogen Co., a corporation of New York.

Reacting on an impalpable amorphous carbide with a nitrogenous reagent, at a temperature above 500°.

1,071,847.—MAGNETICALLY OPERATED CONVEYING AND DISCHARGING APPARATUS. Wylie Gemmel Wilson, Elizabeth, N. J., assignor to W. G. Wilson Co., Montclair, N. J., a corporation of New Jersey.

An annular chambered conveyor casing having an inner circumferential wall of magnetic conductivity, an endless conveyor mounted in said annular chamber and provided with pocket forming disks and soft iron pieces; and a rotatable magnet structure mounted in the space inclosed by the inner circumferential wall of the annular chamber.

1,074,192.—SLIME DEWATERING GRAVITY DEVICE. Ira F. Monell, Boulder, Colo.

A pulp classifying and slime thickening apparatus comprising a tank having a long narrow settling chamber divided into a plurality of compartments each of which has an opening in its bottom, the upper end of said narrow chamber merging into a flaring current chamber, the opening between said current chamber and settling chamber being reduced, a plurality of baffle boards depending into said current chamber and arranged over the compartments of the settling chamber and means for restricting the capacity of said openings.

1,074,114.—CASE-HARDENING PROCESS FOR ARTICLES OF IRON, STEEL AND STEEL ALLOYS. Frederico Grolitti, Turin, Italy, assignor to Societa Anomina Italiana Gio. Ansaldo Armstrong & Co., Genoa, Italy.

A process for case-hardening objects of iron, steel, and steel alloys, comprising the following steps: packing the objects to be treated in granular carbon in a retainer, heating the container from an external source, passing a current of air through the carbon, and adjusting the rate of flow to obtain the desired concentration of carbon in the treated article; the temperature and duration of the treatment being kept constant.

1,071,870.—CENTRIFUGAL CONCENTRATOR. Martin Prior Boss, San Francisco, Cal.

A revolving separating basin comprising an outer pan having peripheral discharges, an inner pan separated from the outer pan to provide a water chamber between the two pans and a crown ring on the top of the outer pan and shelving inwardly over and beyond the rim of the inner pan, and separated from the top of said rim to provide an annular space for the outflow of the concentrate separated from the pulp to said inner pan, against the inflow of an excess of water supplied to the water chamber, said crown ring having a conical inner wall with a continuous outward slope from its lower to its upper edge.

1,071,714.—SLIME CONCENTRATOR. William F. Deister, Fort Wayne, Ind.

Combination of a table having a mineral discharge edge in its front side, and inclined downwardly from its head and upwardly from its rear side, continuous or unbroken riffles, extending from the head diagonally across the table toward the front side thereof; means for feeding pulp directly into the channel intermediate the riffles, means for the direct discharge of concentrate from the table at the termination of the riffle channels extending from the point of feed, and means for so vibrating the table that the concentrate will move along the riffles and away from the rear side of the table.

Book Reviews

QUANTITATIVE ANALYSIS. By Edward G. Mahin. P. 511. Ill., index. McGraw-Hill Book Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price, \$3.

Mr. Mahin, associate professor of chemistry in Purdue University, in writing this text-book on chemistry has attempted "to present a theoretical and practical discussion of the subject, sufficiently simple to be comprehended by the average student but not so elementary as to destroy his self-respect." The first half of the book contains a general discussion of the objects and methods of quantitative analysis, and the remainder is devoted to methods of analysis of industrial products and raw materials. It appears to be a good, general text-book which may be especially useful to students of industrial chemistry.

A READER OF SCIENTIFIC AND TECHNICAL SPANISH. By Cornélio De Witt Willcox. P. 588. Ill., vocabulary. Sturgis & Walton Company, New York, 1913. For sale by the *Mining and Scientific Press*. Price, \$1.75.

As is indicated by its title, this book is intended for the use of students in colleges and technological schools who are engaged in the study of the Spanish language and expect to practice engineering in countries where Spanish is spoken. The book consists of nineteen chapters, each of which is devoted to a technical subject, such as: physics, chemistry, electricity, steam, compressed air, mining, bridges, railways, automobiles, aeronautics, etc. The chapters are abstracts or excerpts from Spanish publications, chiefly from 'La Física Moderna.' They are elementary in character and written in popular style, but afford an excellent opportunity for acquiring a technical vocabulary. The terms used in the chapter on mining are not those in common use in Mexico, so this part of the vocabulary would be of little assistance to mining men in that country, although the technical terms may be in use in Spain or the Philippines. The 'Reader' is a good text-book for technical students in high-schools and colleges, and also for engineers who are beginning the study of Spanish.

THE SAMPLING AND ASSAY OF THE PRECIOUS METALS. By Ernest A. Smith. P. 460. Ill., index. Charles Griffin & Co., Ltd., London, 1913. For sale by the *Mining and Scientific Press*. Price, \$4.50.

Assaying is a branch of metallurgy which has attracted large numbers of students, consequently a good number of works have been published on the subject. It may be said that the majority of them have been worth while, and the one under review can be included in that list. The author, who is connected with the Royal School of Mines, London, states that his book is primarily intended for students, having been written chiefly at the request of his old students. In the design and equipment of assay offices, modern practice is discussed including the style of building, machinery, and the latest furnaces, including coke, coal, and gas-fired, are described. How to use a balance properly is explained in a simple manner. Sampling ores and other products has been discussed at great length in technical papers, and in this volume the author has given late practice. While given at length, the operation of assaying contains nothing new; but the sampling and valuation of gold and silver bullion by dry and wet methods has been carefully done. Chapter XXII covers the assay of auriferous and argentiferous metallurgical products, chapter XXIII is on laboratory work in a cyanide mill, while the last 36 pages thoroughly deal with platinum and its allied metals.

METAL-MINE ACCIDENTS IN 1912. Compiled by Albert H. Fay. Technical paper No. 61. P. 76.

ERRORS IN GAS ANALYSIS. By G. A. Burrell and F. M. Seibert. Technical paper No. 54. P. 16.

THE USE AND MISUSE OF EXPLOSIVES IN COAL MINING. By J. J. Rutledge. Miners' Circular No. 7. P. 52.

NOTES ON THE PREVENTION OF DUST AND GAS EXPLOSIONS IN COAL MINES. By George S. Rice. Technical paper 56. P. 24.

COAL-MINE FATALITIES IN THE UNITED STATES. October and November, 1913. Compiled by Albert H. Fay. P. 22 and 23, respectively.

MINE-ACCIDENT PREVENTION AT LAKE SUPERIOR IRON MINES. By Dwight E. Woodbridge. Technical paper 30. P. 38. Ill. A large number of men are employed, and an enormous tonnage of ore is mined from the properties in this area, and an interesting account is given of occurrence of accidents, and what is being done for their prevention.

TESTS OF PERMISSIBLE EXPLOSIVES. By Clarence Hall and Spencer P. Howell. Bulletin 66. P. 313. Ill., index. This paper gives the results of tests of all permissible explosives tested by the Bureau of Mines experiment station at Pittsburgh, between May 15, 1909, and March 1, 1913. An explosive is considered permissible for use in coal mines when it is similar in all respects to the sample that passed the tests required by the Bureau, and when it is used in accordance with the conditions prescribed. A fee of \$150 is charged for testing any explosive.

Industrial Progress

IMPROVED HUNTINGTON CENTRIFUGAL ROLLER QUARTZ MILL

Huntington mills are useful and efficient machines for crushing fairly hard or soft ores which have been broken to 1 to 2-in. size, and reducing this to as fine as 50 mesh. The mills are easily erected, and are especially useful for small mines producing such ores. They are good amalgamators, and recover a high percentage of gold inside without unnecessary flouring of the quicksilver. Some faults with the old type of mill are the following: (1) roller shells work loose

and fall down; (2) the screen discharge is imperfect; (3) excessive wear of the ring die directly under the feed spout; (4) short life of roller shells and ring dies; (5) uneven motion of the roller shells due to wood wedges; and (6) poor means of lubricating the roller shafts, resulting in regular shut-downs to oil up and other troubles. The improved Huntington mill, manufactured by the United Iron Works of Oakland, California, claims to eliminate these faults by (1) dispensing with wood wedges and using a roller head turned on a strong taper to fit the bored taper of roller shell; (2) the screen discharge is all around the mill housing instead of covering one-half of it; (3) a central feed is supplied which discharges ore equally in front of each roll, making even wear; (4) roller shells and ring die are double the usual thickness, and are forged and rolled chrome steel; (5) shells and die are machined all over; and (6) an oil hole extends right down roller shafts and a cross hole drilled to meet this one near the top of the roller head sleeve, and by a spring grease cup the shafts are lubricated continuously for 24 to 48 hours, and only feeds while the mill is working. Standard sizes of these mills are 3½, 5, and 6 ft. diameter, weighing 7000, 14,000, and 22,000 lb., and with capacities of 10 to 20, 20 to 40, and 50 to 100 tons per 24 hours. This firm also makes an ore feeder of the Challenge type suitable for feeding its mill.

The CALIFORNIA EXPLORATION Co. has let the contract for the New Plymouth Consolidated mill. It will include Demarest stamps, two 8 ft. by 2-in. Hardinge pebble mills, and Isbell vanners.

EDITORIAL

WE print this week the first part of an elaborate paper upon the geology and ore deposits at Globe, written by Mr. W. L. Tovote, whose earlier papers on the Clifton-Morenci and other Arizona copper mining districts will be recalled by our readers with pleasure. The paper illustrates not only the careful geological work that is now done as part of the routine of American mining companies, but in its free publication also evidences the generous attitude of the Southwestern mining companies toward making public facts of general interest and value.

SAFETY is being made the first consideration at an increasing number of works, and at the mines and plants of the Nevada Consolidated Copper Company every effort is being made to impress upon officers and men the paramount necessity of guarding life and limb. A convenient book of rules has been prepared and printed in English, Italian, Greek, and a Slavic language, for circulation among the men. We print an extract which exemplifies the practical character of these regulations. A monthly bulletin is also published. In it each accident is recorded with full details, and, where necessary, simple sketches showing how similar accidents are to be avoided.

CABLE advices announce that in the case before the Judicial Committee of the Privy Council, involving the question of infringement of the Elmore process by that of Minerals Separation, decision has just been given in favor of Minerals Separation. The matter was discussed in our London correspondence of February 28, and earlier. While some of the points involved were adjudicated in November 1909 in action before the House of Lords, in which case Minerals Separation won, the present decision is on appeal in the interest of the Elmore process from a decision rendered July 24, 1911, in New South Wales, and involves additional matters. The court of last resort now holds that the Elmore patent is valid, but "limited to any process of separation in which oil is adequate in quantity and of sufficient tenacity to entrap or coat mineral particles in a watery pulp and to hold or carry such particles until separation is effected." It is also held that "respondents do not either directly or indirectly use the invention claimed by appellants, but a process essentially distinct, and that there is no infringement." In the absence of the full text of the decision it is im-

possible to tell exactly what weight to place upon the phrase "entrap or coat." The fact that the quantity and tenacity of the oil is mentioned seems to indicate that the court had in mind making sharp distinction between the bulk oil flotation of the Elmore process and froth agitation of the Minerals Separation.

SPELTER production in the United States in 1913 amounted to 346,676 tons, according to figures collected for the United States Geological Survey, by Mr. C. E. Siebenthal and printed this week. Comparison of this figure with the 345,575 tons estimated by Mr. Siebenthal at the first of the year and printed in our issue of January 3 and the 356,146 tons estimated by a New York contemporary January 10, would seem to indicate that the staff of the Geological Survey is in closer touch with the metal producers than might be inferred from the repeated insistence of the journal in question that the opinion of the Survey statisticians as to metal markets is of no consequence.

COMPLAINTS of the agriculturalist against the miner are old as industry. Agricola wrote that "the strongest argument of the detractors is that the fields are devastated by mining operations" and quotes many an ancient author. None the less, mining has gone on steadily, as it will doubtless continue to do. The world cannot get along without either grain or metals and undue waste in either agriculture or mining should be stopped. Without question, it will be decreased as attention is directed to the matter and to the possibilities of improved methods of work are learned. The dredge men and the valley farmers have been in controversy both in California and Victoria, and we reprint this week the substance of a report made to the Victorian Parliament upon the matter. It must be confessed that it tends strongly to confirm the claims made against the dredge men. If, however, that represents the facts it is important to have it fully and fairly stated. Our own impressions are to the effect that destruction of valuable farming land by gold dredging is relatively insignificant.

Louis Janin

Death of Louis Janin at Santa Barbara last week removes another of that group of brilliant engineers who contributed so mightily to placing mining in the western United States upon a sound technical basis. In our semi-centennial number, May 21, 1910, Almon D. Hodges, Jr., another member of this group, gave a graphic picture of San Francisco and the Comstock when the latter was at its greatest productivity. It was a period when silver was apparently to be picked up by the most inexpert, as had been true of gold before, and when the professional engineer had to climb over a mountain of prejudice if he would reach the lonely heights of the few who could demand big fees for advice on technical matters. There were not many who were soundly prepared to give such advice, and

among those few Louis Janin was by no means least. Of French descent, American born, educated at Freiberg, and drilled in mining as actually conducted in what was then the greatest scene of mining activity in the world, Louis Janin built up a reputation for skill and sound judgment that placed him in the very front of the profession. He examined and reported upon many of the properties throughout North America that have since become most famous, and while still young for such a mission he was called to Japan to assist in re-making the mining industry of that empire, even before the revolution, when the Shogun was making the first attempts to acquire for that ancient country the best of the knowledge and skill of other lands. Janin's advice was sought on all the big mining lawsuits so long as he remained in practice, and even in those later years when at the pleasant little ranch at Gaviotta or among the idlers at Santa Barbara he, as he jokingly referred to it, was "waiting to die," many a request for advice and help found its way to him from the largest interests. Louis Janin's counsel was sought because it was always honest, it was always based on real study, and it was illuminated by wide experience and much reading. His example was a most helpful one. He took the responsibilities of his profession seriously. To him mining engineering was no mere glorified manner of scrambling into wealth, but was ever a field for serious investigation and for exercise of discriminating, responsible judgment. He held his assistants to hard work. "Get the facts," was his repeated injunction, and the men who have gone out from his service to make brilliant successes in their profession, among whom Mr. H. C. Hoover and Mr. John Hays Hammond may be mentioned, have shown always the ability to get the facts which is the first requisite to any sound report on a property or a business venture.

Louis Janin was a many sided man, and neither space nor time is available here for more than this brief announcement. At another time we hope to tell connectedly the details of his most interesting life and career. For the present we express sympathy with his relatives and friends and our pleasure in belonging in a calling that breeds up men with such professional ideals.

Mining in China

Interest in China has been greatly stimulated of late by a joint arrangement between the Standard Oil Company and the Chinese government to develop the petroleum resources of western China, and by the arranging for a loan of \$20,000,000 under the auspices of the American Red Cross Society, which is to be expended in conservancy work for the prevention of floods along the course of the Huai river. This work is to be done by the J. G. White Corporation, which has an established reputation for engineering works of large magnitude. The Red Cross Society and other

philanthropic organizations have for many years been raising considerable sums for the relief of flood sufferers in China, and it is an exhibition of admirable intelligence which prompts the expenditure of money to prevent the occurrence of suffering and at the same time produce revenue, since the crop yield in the affected region can be greatly increased by proper irrigation. Aside from its aspects of humanitarianism and good business, this scheme has an even more important bearing on international relations. The great American public knows little about China and cares less, being content with the idea that it is the point of origin of 'chop suey' and laundrymen, and is largely inhabited by opium smokers and missionaries. As a matter of fact, 'chop suey' is unknown outside the American 'Chinese' restaurant, men do not do laundry work in China except for foreigners, opium smoking has been almost suppressed, and the missionary, with his schools and hospitals, has been the most effective agency in the renaissance of that ancient empire. This lack of interest is based on a lack of commercial relations, and American participation in the recent loans to China was a failure, largely because Chinese bonds could find no market here, our Government did not officially endorse the American banking group, and there was no public sentiment which would urge the Government to do so. The patronage of the far-reaching organization of the Red Cross Society should be able to reach that best possible market for bonds—the small investor who is not trading in the general market; and the widespread holding of Chinese securities should develop in time a keen interest and more exact knowledge of China in the American public.

The details of arrangements made by the Standard Oil Company are, like most of the operations of that concern, shrouded in obscurity. Out of the maze of contradictory statements which have been made may be gleaned the fact that a joint company is to be formed in which the Chinese government will receive a minority interest (said to be 40 per cent) in return for securing such lands, working rights, and rights-of-way for pipe-lines and railways as the Company may require. Geologists and drill crews have already been sent to Shensi, where the promising property at Yen Chang (110° E., 36°30' N.), formerly developed by Chinese and Japanese, has been turned over to the new Company. From this point west, northwest, and south, for great distances, is an area which is but little known, and which offers some promise at least of developing oilfields of considerable importance. In Ssu-chuan the Chinese have for centuries been using the natural gas obtained from deep brine wells for the purpose of evaporating the brine, but the amount of oil here obtained is insignificant. It must be remembered, however, that the Chinese sought for brine, not oil, and a better-directed search may have different results. In any case, the action is significant, for three reasons: it indicates the confidence of a well informed

business organization in the republican government, it is a unique instance of a partnership between an Oriental government and a foreign corporation, and it may lead up to the development of a large new supply of fuel oil and cause international readjustments that cannot now be even guessed.

Despite these important happenings, mining in China languishes as a whole. A single exception to this must be made, for coal mining prospers, especially the mines that are under foreign management. From now on the coal industry will take care of itself, for the Chinese are familiar with the profits that have been and are being made, and are equally familiar with coal-mining methods. Iron mining languishes for two reasons. Whenever money for new railways is borrowed from abroad, a 'rider' is attached to the agreement providing that the equipment must be bought in the country which furnishes the money. As a result, China has become the greatest museum of railroad equipment anywhere to be found. Because of this the Chinese steel company at Hanyang has labored under great difficulties, often being unable to secure specifications on which to bid in competition with foreign makers. The finances of the Company have been so poorly handled that its control has passed into the hands of Japanese bankers. The net result is far from encouraging to those Chinese who consider embarking in the iron and steel business. Of mining for other metals, it may be generally said that the Chinese are unwilling to grant concessions to foreign companies, having learned better by numerous unfortunate experiences, while it is impossible to raise much domestic capital for mining ventures, since there are ample opportunities for investment in enterprises with which Chinese merchants are more familiar.

The most hopeful signs of progress are the recent statements of Chang Chien, minister of commerce and industry. Since 1900, numerous attempts have been made to draw up a satisfactory set of mining regulations, without success. The most important defects have been that the areas allowed to a mining company have been too small, a heavy royalty was demanded, and the conditions under which foreign capital could be invested in mines were so disadvantageous that certainly no foreigner would invest in mines. It is now proposed to increase the area to about a square mile (ten times the former size), to collect a tax on output rather than a royalty, and to permit free dealing in mining shares, which would mean that the control of companies could be secured by foreign investors. The experience of the past two decades indicates that a mine with modern equipment, but under native control and management, has almost no hope of making much profit. If progress is continued along the lines which Chang Chien has mapped out, there is good hope that the backward mining industry of a country of great natural resources may at last be galvanized into productive activity.

OLD DOMINION, LOOKING EAST.

The Globe Mining District, Arizona

By WILLIAM L. TOVOTE

The Globe mining district, Gila county, Arizona, is one of the older mining centres of the Southwest, and has seen boom and depression for more than the last 35 years. It is more flourishing now than it has been for a long time, if ever, but an overboosting at the Miami end for real estate and other commercial purposes tends to turn this boom into a premature depression. Silver mining was the start of the mining industry here, but today copper is paramount. The mines of the district in order of production are the Miami, Old Dominion, Black Warrior, Superior & Boston, Iron Cap, and Gibson. The Arizona Commercial and a few old mines that bid fair to become successful producers are in course of reopening. A number of prospects are worked in a desultory fashion, some of them being of decided merit.

Production and Reserves

The Inspiration Consolidated, with ore reserves upward of 45,000,000 tons and a proposed production of 7500 tons per day, looms large as the probable greatest producer in the future. The Miami and Old Dominion each produce at present about 30,000,000 lb. of copper per year. The former a little more, the latter a little less, but the Old Dominion may possibly exceed the Miami, when the remodeling of concentrator and hoisting plant, now under way, is finished. Black Warrior is now shipping 125 tons of 7% ore per day under leasehold. The Superior & Boston, after prospecting for years the fault that dislocated the Great Eastern vein, has recently picked up the displaced extension and opened a body of promising ore and is getting ready to ship 150 tons per day of about 6% ore. The Iron Cap produces perhaps 600 tons per month of 8% ore besides high-grade copper-glance ore with considerable silver. The Gibson used to ship about 300 tons of

20% ore per month and is now being reopened, after a short shut-down, under new management and getting ready to build a mill and utilize the large accumulations of low-grade ore in the mine and dumps. Arizona Commercial, when ready, should produce about an equivalent of 50 tons of 6% ore per day, but the development has as yet not proved any large ore reserves. The list of probable producers might be increased if some of the prospects, especially at the Miami end, now in the developing stage, prove sufficient tonnage and commercial grades of ore. The district ranks at present third in Arizona in copper production and close to the Clifton-Morenci. With the Inspiration coming into the field and the modern improvements and expansion under way now at the Arizona Copper Co. at Clifton, both districts will contend for a while for this second place, but Globe ought to outdistance Clifton ultimately and even crowd Bisbee closely for first.

Outside of the copper, the silver production of the district should show considerable increase, as several of the older silver mines that gave birth to the camp in the early seventies are worked under leasehold or are in process of reopening, especially the great Stonewall McMillan vein, and the extremely rich ore found locally augurs well for the future, even if some of the veins are rather narrow and the ore bunchy. There are furthermore, besides numerous copper and silver prospects, some small gold veins and a few rather meritorious lead-silver, lead-copper-zinc, and zinc prospects. Vanadium minerals and carnotite also occur.

General Geology

The geological history of the district starts with marine deposits of Archean age, the Pinal schist. A gap in sedimentation between these and the Cambrian points to continental development. The Cambrian

OLD DOMINION, LOOKING NORTHEAST.

shows submerging to deep-sea and subsequent risings; it is represented by conglomerates, silts, shale, limestone, quartzites, and sandstone. The Silurian remains unrepresented in spite of the fact that in the Clifton district, not far away, unmistakable Silurian sediments are exposed; but it must be borne in mind that the upper quartzite series, generally attributed to the Cambrian, is not fossiliferous and might possibly be of Silurian age, especially since the Devonian rests conformably upon it. The Devonian is represented by about 300 ft. of fossiliferous limestone, sometimes gritty at the base, and continues without dividing horizons. The same character of sediments (limestones and calcareous shales with occasional sandy beds) continue through the Mississippian into the Pennsylvanian. Here sedimentation ceases, commencing again only with the roughly stratified creek gravels and lacustrine conglomerates of Tertiary or Quaternary age, here divided into 'Whitetail conglomerate' and 'Gila conglomerate' (Ransome) by an intervening surface flow of dacite.

There have been three main periods of volcanic activity in this district. The oldest antedates the Cambrian and is represented mainly by granitic rocks, named by F. L. Ransome, the Madera diorite, Solitude granite, and Ruin granite. The second and most important, because connected with the ore deposition, is of Mesozoic age and occurred after sedimentation had ceased and erosion had had its turn. It included the great diabase extrusion, followed by a smaller intrusion of diorite-porphry, and another outpouring of great masses of granite-porphry (Schultze granite). The third and last is evidenced by great surface flows of dacite, probably of Tertiary age. There are rocks of several smaller volcanic eruptions in addition to those of these main periods. These include diorite-porphry sills of uncertain age, and basaltic lava flows, one of Cambrian age and resting upon the Cambrian limestone, and one of Quaternary age intercalated in the Gila conglomerate.

Geological Structure

The structure of the district owes its present configuration mainly to the great diabase extrusion, and to subsequent faulting. Whatever faulting and dissection might have existed prior to the Mesozoic period of volcanic activity, has been almost entirely obliterated. The subsequent faulting and that following the dacite outpouring was so tremendous in scope and effect that Mr. Ransome coined the term 'regional brecciation' for the configuration produced by it. A great massive of pre-Cambrian granite to the north of the district, that sends out the two branches, the Apache and Pinal mountains, served as an upholding buttress, but between these granite-schist masses the country collapsed, and irregularly detached masses of sediments descend from their slopes, while a wide fringe of the same sediments less disrupted surrounds them on the outside. The Globe district embraces the Apache and Pinal mountain country, while the Ray district adjoins it on the west slope of the Pinals.

How far reaching an influence upon the structure the diabase eruption had, is best seen from the fact that it added more material to the outer crust of the rocky shell, than had been accumulated during the whole Paleozoic sedimentation above the Archean Pinal schist. The sediments amounted to about 2000 ft. and were disrupted by sills, dikes, and intrusive masses, sometimes bodily shifted and perhaps almost floating in the surrounding masses of semi-consolidated magma. Two columnar sections, Fig. 1, showing approximately the sedimentary column before and after the diabase eruption, explain this better than words.

The reaction from this volcanic cataclysm caused settling of the overburdened surface. Faults began to dissect the country and ore genesis began in fissures. These post-diabasic faults, important as seats of ore deposits, have generally a northeast-southwest course.

A second period of intense faulting followed the outpouring of the dacite. These faults have generally a

OLD DOMINION FAULT PLANE.

northwest-southeast strike and displace the older north-east-southwest fissures. As a rule they are not primarily ore bearing, but have sometimes followed planes of weaknesses produced by diabase intrusions, and might in this case comprise primary ore deposits. At times secondary ore occurs along these faults near their intersection with mineralized veins. The tracing of these relative fault movements becomes more complicated as some of the northeast-southwest faults have been reopened during the post-dacite period of faulting, as for instance the Old Dominion vein. Here the problem is perhaps even more complicated, as some facts (the unequal distribution of diabase sills in foot and hanging for one) point to an existence even antedating the diabase intrusion for that particular fault.

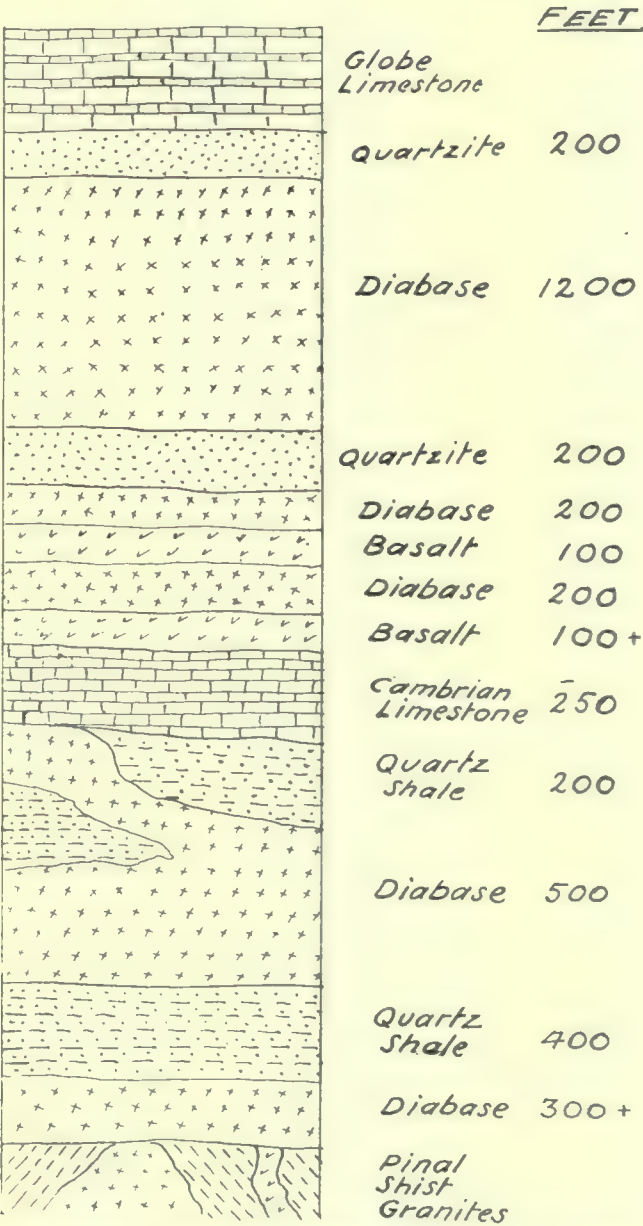

FIG. 1. SKETCH OF SEDIMENTARY COLUMN BEFORE AND AFTER DIABASE ERUPTION. THE DIABASE SILLS ARE NOT UNIFORM, BUT SUBJECT TO CHANGE IN HORIZON AND THICKNESS.

WEATHERING OF THE DACITE AT GLOBE.

Some of the faults have individual throws exceeding a thousand feet (the Old Dominion, for instance, and others might have possibly several times that amount) but it is scarcely possible to arrive at reliable estimates in a country where sediments of originally close proximity may have been shifted 1000 ft. by intruded diabase sills. The post-dacitic fault movement caused concerted step faulting amounting to perhaps 6000 ft. between the Apache and the Pinal mountains. Lower Cambrian sediments top the Apache granite massive at an altitude of about 7000 ft., the top of the Pinals at about the same elevation is granite and schist stripped of sediments, while the lowest (16th) level of the Old Dominion (elevation 2400 ft.) is still in Devonian limestone overlain less than 200 ft. above by the Cenozoic Whitetail conglomerate. On top of this rests normally a dacite surface flow overlain in turn by the oldest rock in the district, except the Pinal schist, the pre-Cambrian Madera diorite, here brought up by overthrust faulting. This marks an overthrust therefore that lifted the block of Madera diorite at least 3000 ft. From this overthrust mass of Madera diorite along Pinal creek to the main massive of the same rock, a distance of about seven miles, stretches an unbroken area of Gila conglomerate screening any further faults or vein outcrops. But, assuming the overthrust angle of between 20 and 30° as constant, this would call for a length of approximately two miles for the overthrust movement, a distance which might coincide with that to the lowest structural depression between Apache and Pinal mountains.

Types of Ore Deposits

There are three types of ore deposits represented in the district: (1) mineralized fault fissures; (2) disseminated sulphide impregnations in fracture zones; (3) irregular metasomatic bodies of secondary ore. The first type was first explored and is generally genetically the oldest. The second attracts more attention at present. The commercial value of the second lies in copper exclusively. For the first type copper is

the commanding metal, but it includes also deposits of silver, lead, zinc, and gold. The third is sometimes so closely linked with the first as to form only a local phase due to conditions of complex fissuring and adaptability of country rock. In this case the secondary minerals are partly at least derived from primary sulphides oxidized in situ, but it forms also an independent type in the Black Warrior and the Geneva mines, where chrysocolla, derived most likely from the oxidation and erosion of the neighboring Miami-Inspiration orebody, replaces the lower horizon of the dacite, here resting on Pinal schist.

Mineralized Fault Fissures

These fissure veins have their main representative in the Old Dominion, the first mine operated in the district, and the one most thoroughly explored. It is

FIG. 2. IDEAL CROSS-SECTION THROUGH EAST END OF OLD DOMINION VEIN. NOTE THAT THE THICKNESS OF THE UPPER QUARTZITE HERE IS APPARENTLY ABOUT 800 FT., FAR IN EXCESS OF THE 400 TO 450 FT. GIVEN BY F. L. RANSOM.

opened by four shafts, named A, B, C, and Kingdon. The first three are in the foot-wall, the last in the hanging wall. Its lowest level is the 16th, about 1400 ft. below the collar of A, the main working shaft.

The Old Dominion vein is not a simple fault-fissure, but a complex system of roughly parallel northeast-southwest veins, which alternately join and separate. The main vein has an individual throw of over 1000 ft. in the west end of the mine, a throw that lessens considerably toward the east, where at the same time its tendency to split in several branches becomes more pronounced. It has a dip of about 65° to the south, while generally the northeast-southwest veins of the district dip rather to the north, with dips from 35° or 40° up to nearly vertical. Outside of the system of veins linked with the Old Dominion there are a number of similar systems in close proximity as well as scattered over the district, but most of them have not received more than scant attention.

The East End

Along the eastern extension of the Old Dominion system of veins and some of its branches are situated the Grey mine, Copper Hill mine, Iron Cap mine (Iron Cap and Williams shafts), the Eureka shaft of the Arizona Commercial Copper Co., and the Superior & Boston. None of these mines has developed orebodies approaching in size or richness those of the Old Dominion. There is a gradual change in character of ore from the west end of the Old Dominion toward the Grey mine that points to a difference in genesis, while the Grey mine and the mines farther east are surprisingly similar. The outcrops here are as a rule either in diabase or in some of the Cambrian quartzites, though sometimes at the contact of these two rocks.

Where diabase is the country rock the outcrops consist of discolored and weathered diabase, sometimes containing lenses of rusty quartz and stained brown or black by oxides of iron or manganese. The uppermost part of the veins, sometimes down to several hundred feet, are barren, with the exception of some minor veins that contain considerable in the form of chloride and bromide, more rarely native silver, at the grass roots; but these veins have not shown much in depth, so far as they have been tried. Their prospecting does not allow of a final conclusion, but they might possibly form a type somewhat distinct from the general copper veins notwithstanding that they blend decidedly into each other. Manganese stained outcrops are a good indication of silver.

The copper veins proper are, as mentioned before, usually barren and leached in their upper levels where diabase forms both walls. Farther down, oxidized copper minerals begin to appear as well as the oxides of manganese and iron. The gangue as a rule is altered diabase, whose feldspar is first saturated with and then replaced by copper salts. Inclusions of brecciated sediments in the vein usually cause a concentration of metals. The copper minerals are principally mala-

chite and chrysocolla, azurite being rare.

Sometimes a transition zone with native copper and cuprite appears at the bottom of the oxidized zone, but this is lacking in many cases. Where quartzite or limestone, and to a lesser degree, where a diabase-sediment contact forms the walls of the vein outcrop, copper ore begins right at the grass roots. Sometimes traces of diabase mark the vein in these sediments, but as a rule the existence of intrusive diabase dikes is rather hard to prove in the zone of surface alteration. The copper minerals are chrysocolla, malachite, cuprite, brochantite, melanochalcite, and copper pitch. Native copper, so plentiful in the Old Dominion mine, is rather scarce in these veins. The metallic minerals replace and pervade the crushed sediments, apparently causing a concentration of silica in quartz grains and first attacking the calcareous or aluminous components of the country rock, but ultimately even replacing apparently pure quartz. Veinlets of manganese oxide (wad) accompany the ore and micaceous hematite or limonite are practically universally present, intimately mixed with the ore or disseminated or in stringers through the sediments. Zones of enrichment show large accumulations of siliceous iron oxide, usually limonite, with irregular bunches of copper minerals throughout this mass. Where these veins change from a quartzite to a diabase country rock in depth, a barren zone usually follows below the quartzite, sometimes for several hundred feet at a stretch, but micaceous hematite continues in most cases. Exceptionally, the case has been observed where the vein outcrop in quartzite was barren, the ore beginning in the diabase below, but this vein might possibly belong to a different period of mineralization.

In depth these differences of mineralization of the outcrops disappear and the veins are dikes of diabase between walls of sediments on both sides, diabase and sediments, or diabase on both sides. The gangue is prominently micaceous hematite with subordinate quartz, siderite, dolomite, or calcite. The ore is a mixture of pyrite, chalcopyrite, and bornite in this gangue. Chalcocitization is as a rule not much in evidence, but exceptionally bunches of almost pure chalcocite are found, accompanied as, for instance, at the Iron Cap by much silver due to an admixture of argentite. Here an imitation of structure approaching pseudomorphosis after hematite can be observed.

The Old Dominion Mine

The Old Dominion vein has been considered a fault-fissure with diabase foot and sedimentary hanging wall. This is not exactly correct, but approaches the fact, as an intrusion or sill of diabase at least 1200 ft. thick forms the foot-wall for a great part of the mine. But actually the vein can be included between diabase foot and sedimentary hanging, diabase foot and hanging, or sedimentary foot and diabase hanging wall. It contains three ore-shoots as far as explored: the central orebody—the oldest and biggest—and the east and west orebodies more recently opened. The central ore-

body has an exceptionally strong surface cropping of silicious limonite between diabase foot and Devonian limestone hanging. The other two show no surface indications.

The east orebody approaches a simple fissure vein in character. Hematite is not abundant, in fact rather scarce. The gangue is an intrusive diabase dike with inclusions of crushed sediments, principally quartzite. The diabase is not everywhere easily recognizable and quartz grains included in it sometimes suggest the admixture of an acid porphyry. But I have never been able to identify acid porphyry beyond a doubt, and usually the quartz grains, sparingly as they occur, are of rounded outline or in seams, being therefore probably either of sedimentary origin included in the fault breccia or vein quartz.

FIG. 3. IDEAL CROSS-SECTION THROUGH EAST OREBODY, IN THE LOWEST PRESENT WORKING, SHOWING THE DIABASE DIKE AS THE ONLY SEAT OF ORE.

The lowest level, the 16th, has a Cambrian limestone foot-wall and Cambrian upper quartzite hanging wall, the former not altered at all, the latter slightly recrystallized and invaded by sulphides only for a few feet from the vein, if at all. Between both lies a diabase dike up to 100 ft. thick, and this dike contains the ore. Sulphide impregnations and small veinlets extend fairly well all through it, but along certain zones marked especially by kaolinization and serpentinization rich shoots of bornite, chalcopyrite, and pyrite occur. These sulphides penetrate included slabs of quartzite as well as the diabase dike.

While the oxidized part of the vein, except where limestone forms the hanging wall, parallels very closely the veins farther east, both the transition zone of native copper and cuprite as well as chalcocitization are very prominently developed. The sedimentary blocks in the vein show a lagging behind the diabase; that is, they parallel the barren diabase and ore-bearing quartzite outcrops farther east. Oxidized ore appears

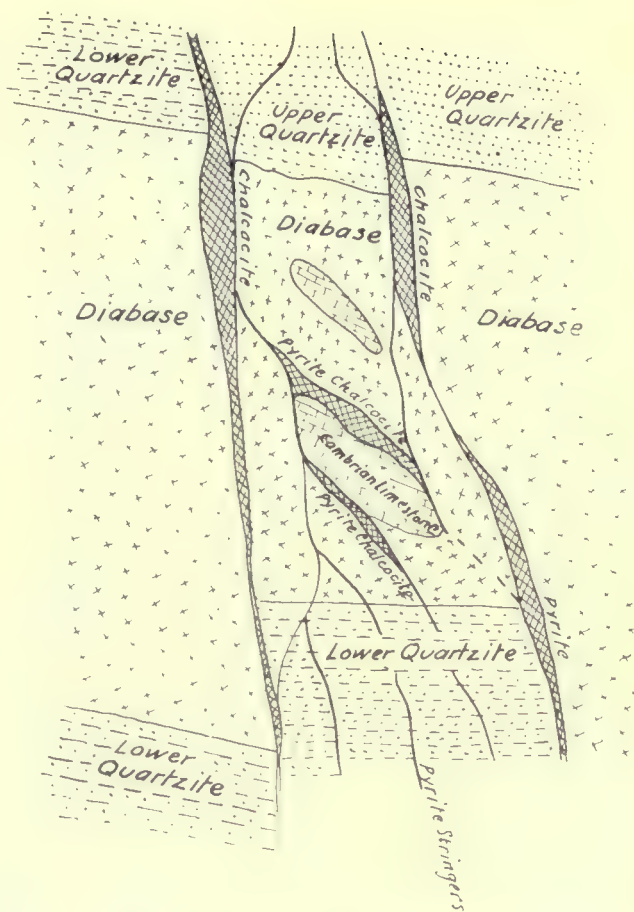

FIG. 4. IDEAL CROSS-SECTION THROUGH THE OLD DOMINION IN LOWER LEVELS OF THE CENTRAL PART OF THE MINE.

in the diabase at greater depths and then is not as rich as in the sediments, which seem to have absorbed by migration and replacement a great deal of the ore originally contained in the diabase. Chalcocite ore in diabase occurs side by side with native copper-cuprite ore and even malachite in the quartzite, and rich sulphides in the quartzite parallel pyritic ore in the diabase.

The central orebody differs from the east orebody in that bornite is not found at all here, while it is almost paramount there. Chalcopyrite is exceedingly rare. The sulphide zone starts in with secondary chalcocite and grades into pyrite. Native copper is frequently intergrown with chalcocite in the transition zone of the vein, and sheets and flakes of the metal impregnate the diabase country rock often for considerable distances. The central and west orebodies also diverge widely from the straight fissure vein type of the east orebody, inasmuch as a number of parallel veins approach the main vein from the hanging wall and the main ore-shoots frequently extend away from the foot into the hanging wall country.

Structurally the west orebody is very complicated in consequence of intricate step-faulting. These faults, while attaining throws of 400 ft. each along two main planes about 1000 ft. apart, are accompanied by numerous smaller faults and seem to represent one single movement. They converge north of the vein, probably

FIG. 5. IDEAL GEOLOGICAL PLAN OF FAULTED WEST SIDE OF OLD DOMINION VEIN ABOUT THE TWELFTH LEVEL.

joining there, and diverge to the south. Still more intricate becomes the disruption of the vein by a reopening of the Old Dominion vein contemporaneously with the cross-faulting. Along the 16th level of the Old Dominion there is from east to west the following horizons, partly due to this faulting: (1) rich primary sulphides, bornite, and chalcopyrite (east orebody); (2) lean pyrite (central orebody); (3) chalcocite pyrite (west orebody); (4) malachite and oxidized ores (downthrown part of west orebody). The west orebody is a close parallel to the uppermost part of the central orebody, that caused the Old Dominion to be classed as a replacement deposit. Here as there Devonian limestone occurs in the hanging wall, which accounts for this abnormal development of the vein. This limestone has been altered over areas up to several hundred feet square, to hematite and limonite grading through increasingly silicious impurities to

rusty chert and sand and soft iron-stained leached-out calcareous clay. Dike-like masses of white or yellow kaolin occur frequently, also sheets or dikes of loose friable micaceous hematite. Both of these are sometimes linked. Except for the occurrence of hematite the type is practically the same as the Bisbee orebodies. Since dikes and sills of diabase are sometimes recognizable beyond a doubt through this zone of alteration, I consider the kaolin and hematite dikes as alterations of, or indications for, similar intrusive masses. The ore occurs as irregular masses in this altered zone and is frequently terminated rather by economic considerations than an actual lack of admixed copper. The change from altered to unaltered limestone is more frequently abrupt than gradual.

The pronounced difference in throw be-

FIG. 6. IDEAL CROSS-SECTION THROUGH WEST END OF OLD DOMINION VEIN, SHOWING REOPENING OF THE FAULT AND OVERTHRUST MASS OF MADERA DIORITE.

FIG. 7. PLAN OF FAULTS.

FIG. 8. CROSS-SECTION OF FAULTS.

tween east and west end of the Old Dominion vein is most easily explained from the fact that a second fault joins it near the Grey mine. Between these two faults a block of ground, triangular both in horizontal and vertical section, has dropped down. Where both faults join, the throw is eliminated and the vein changes dip. It is surprising that the joining of the two faults has apparently not produced any noticeable enrichment, and that the joining fault, which is most probably of the same age as the Old Dominion, has not been found ore-bearing where intersected. But since very little work has been done on it, the established facts are not necessarily final.

Of the number of parallel veins partly connected with the Old Dominion system and explored in the same mine, I might mention the Maggie, Josh Billings, Kirkey, Buffalo, Nevada, and No. 3, all of which have produced ore. Usually those that were rich near the surface have proved disappointing in depth, and some vice versa. Some of these minor veins depart slightly in character from the main vein by lack of hematite and increasing content of pyrite and quartz, and were probably formed at a period slightly later than the Old Dominion.

The Pinal Schist Area

The No. 3 vein is probably identical with the Great Eastern vein of the Superior & Boston. A very flat dip to the north (40°) is a prominent characteristic of both. Of the same type are the veins in the Pinal schist area of the Pinal mountains, between Globe and Ray, including the Gibson, Cole & Goodwin, Bobtail, Independence, and numerous other prospects of surprisingly similar characteristics. Their similarity with the Great Eastern, twenty and more miles distant, is brought home especially where this vein has Pinal schist for wall rock.

The veins in the schist area are conspicuous by a lack of surface indications. The whole area has been apparently eroded very rapidly and this erosion outstripped oxidation. Outcrops of rusty cavernous quartz are sometimes found, but usually the veins can be traced only by outcrops of light yellowish silicious schist-breccia contrasting with the general silky gray color of the sericite-schist. Sulphides begin practically at the grass-roots, chalcocitization is almost lacking, and pyrite, chalcopyrite, and occasional bornite are the predominant minerals. Hematite is found.

The Bobtail, a prospect at present idle, is very exceptional for this district in mineralization because of having hubnerite, MnWO_4 , and a gray copper ore, either tennantite or more likely enargite, besides the usual sulphides in a very quartzzy gangue. Sphalerite is found in most of these veins, which form a connecting link between the copper and zinc veins of the district. The Gibson is the only one of this group that has produced successfully until now.

Zinc-Lead Veins

The zinc-lead veins are bound to diabase zones and

are all in the first stages of prospecting. The gangue is quartzzy and the mineralization varies from straight sphalerite to galena-sphalerite-pyrite with occasional chalcopyrite. They are usually narrow, but well mineralized, and include among their number rather promising prospects. They are prominent around Pinto creek, especially in Powers gulch; but are represented also in the neighborhood of the Old Dominion. The zincblende is of the dark black as well as the resinous variety.

Sometimes the lead prevails over the zinc in the composition of these veins, and in that case silver is liable to be an important accessory, especially in the oxidized zone. The outcrops in this case are usually less iron stained, but vanadium compounds are found frequently, mainly vanadinite, but if copper minerals are present cuprodesloizite is also.

Copper Veins in Schultze Granite

The second period of mineralization, that has its most important representative in the Miami-Inspiration orebody, has formed also vein deposits. These have up to now not attained commercial importance, and are as a rule narrow veins in the Schultze granite area containing stringers of vein quartz and chalcopyrite in a gangue of crushed and kaolinized granite-porphry. Chalcocite occurs rather pure, probably as a secondary mineral. The oxidized zone is rich in azurite in contradistinction to the above mentioned veins where azurite was conspicuous by its absence.

Gold Veins

These are small veins of usually quartzzy gangue. The quartz is very cavernous, probably due to leached-out pyrite, but not necessarily iron stained. Sericite is common, lead occurs sometimes.

(To Be Continued.)

In drilling for artesian water at Casiguran, Sorsogon, in the Philippine Islands, the government officials in the Bureau of Science have found gold in the rock cuttings at a depth of 250 to 300 feet. Colors were obtained by panning crushed samples, and the residue after panning assayed P5.30 per ton. The driller's log showed the well to be a sand for nearly its entire depth of 520 ft., excepting the rock mentioned between 250 and 300 ft. This consists of pumice, obsidian, basalt, and a felsitic to porphyritic light-colored rock. The gold is mostly free and very fine. It seems that the well passed through the edge of a volcanic flow or fine volcanic breccia mixed with pumiceous volcanic tuffs and alluvial sands. The rock containing the gold has been impregnated with solutions carrying silica and other minerals. Gold has never been reported from this district before, and this constitutes a recent discovery.

West Africa is now importing its own silver coins from England, which will eventually displace the British silver coinage.

The Victorian Dredging Industry

The long looked for report of the special board appointed by the Victorian government to inquire into matters connected with and arising out of dredging and sluicing for gold, and other metals, in that state, was presented to Parliament January 30. Its effect upon the industry is likely to be serious. On most points the report is unanimous, although, as the chairman (W. Davidson) mentions in a note to the Premier, accompanying the report, such unanimity was arrived at by a series of compromises; there is, however, a minority report, signed by three members of the board, in which the maximum of solids permissible is as high as 450 gr. per gallon, against 100 gr. in the majority report. The principal recommendations of the board are that no dredging leases should be granted for land of a value over £3 per acre, that 100 gr. of solids in suspension should be the maximum permissible, that no leases should be granted for dredging or sluicing with respect to river beds or banks, nor any leases within a chain of any river, that resoiling should be to a depth of 2 ft., and that the Sludge Abatement Board should have plenary powers over all dredging and sluicing leases. It is also recommended that no reasonable effort should be spared to reserve good land from destruction by dredging or sluicing.

Effect of Ancient Workings

The report traces the development of the industry in Victoria, and of the government policy in relation thereto. Long prior to the development of bucket-dredging for gold mining, the effects of gold mining generally, and more especially of shallow alluvial digging and sluicing, on watercourses and agricultural lands, had called for serious consideration. In the course of its investigations the board encountered numerous instances in which present levels were several feet higher than the original surfaces of extensive alluvial flats. A notable and typical instance was that of the Sandy Creek valley. The whole of this area had, since the discovery of gold in Sandy creek, been covered with deposits, resulting indubitably from alluvial gold digging in its primitive ways, to depths ranging up to 4 ft., which, in the passing of years, had developed a soil, now chiefly utilized for the fattening of cattle. Bucket dredging is, and has been, almost entirely conducted in Victoria, under leasehold tenures, granted by the Department of Mines. Since 1900 there have been issued 176 bucket dredging leases, apparently for an aggregate area of 20,704 acres, while there are now in existence 52 such leases, of a real aggregate of 9830 acres. As the report indicates, however, it does not follow that the difference in the totals (10,874 acres) consists of land that has been dredged, as, owing to the consolidation of numbers of the original leases, many areas occur twice in the major aggregate.

In the earlier stages of the operations in river beds

and adjacent lands, there do not appear to have been any restrictions placed on the dredging owners as to the disposal of the dredged material after its passage through the machine, and, so far as the board had been able to ascertain, in no case was any effort made to restrict the amount of polluting matter that might pass into and down the district main water courses, or to restore in any degree the surfaces of dredged areas. Since the creation of the Sludge Abatement Board, it has been the practice to include in all dredging leases certain covenants, designed to secure water courses and lands against pollution or injury from dredging operations. It is only since 1906, however, that these covenants have been embodied in full in dredging leases. The duty of seeing that they are observed falls upon three official inspectors of dredging, who make periodic inspections of all dredging and sluicing operations within their respective districts, report to headquarters as to the observance of covenants, and, within limits, give directions to dredge masters as to the disposal of debris, and the control of effluent water. It cannot be said (adds the report) that the board considers the relations existing between these officers, the Department, and the Sludge Abatement Board, as being on a quite satisfactory basis.

Attention is called to the anomaly of Crown land, for which no compensation is sought, being leased for dredging at a rental of 5s. per acre per annum, while adjoining it, and included in the same mining lease, is land only lately acquired as freehold from the Crown, for which the owner receives compensation at the rate of £9 per acre, and the opinion is expressed that considerable revenue might have been derived by the state if an equitable charge had been made for the Crown lands required for dredging. Until recently, the Department of Mines paid no heed to the nature or value of the lands, whether Crown or freehold, leased by it for dredging; but early in 1909 it was decided that no land of a value of £3 per acre and upward should be so leased. This restriction is not embodied in any act of Parliament, but is being given effect to by ministerial order only.

Original Condition of Land

Referring to the Ovens and Buckland Rivers district, the report says that prior to the inception of bucket dredging, the whole of the flatter areas was covered with good alluvial soil, of varying depths, while in exceptional plots there are evidences in it of great productivity for many of the forms of agriculture. A considerable portion of the valley was worked, and very likely reworked, by the alluvial gold diggers of the fifties and sixties, to the destruction of the original timber and vegetation, the honeycombing of the land with shafts and drifts, and the part upturning of the surface. There are also evidences of hydraulic sluicing, on both the flats and the adjacent

*From the *Australian Mining Standard*, February 5, 1914.

terraces, having been extensively carried on, and although, as is visible in many places, a fairly dense afforestation followed on the abandonment of the valley by the diggers, in many instances the value of the land for agricultural purposes must have been greatly reduced before dredging began. The board admits that it found proofs, not only that efforts are being made by many dredge owners to comply with the re-soiling conditions of their leases, but also that the deposition of sludge is not always and permanently destructive. In one instance, on the Buckland, the Buffalo dredge had resoiled an area of four acres, with good results. A portion of the four acres was sown down, which yielded 2½ tons of hay to the acre. The cost of re-soiling, however, is regarded as being heavy, about £54 an acre. As to the pollution of the Loddon river, the board does not hold dredging solely responsible for it.

Pollution of Streams

In the Castlemaine-Loddon district the board investigated numerous complaints of water pollution by the dredges. The board found that the effluent from a dredge, the Guildford, was being discharged directly into the Loddon river. In the Ovens and Buckland valleys, at Sandy creek, and in the Loddon, below Campbell's creek, lands are now being dredged which the board is strongly of opinion should not have been leased for such purpose. There may be enumerated the leases of the Tewksbury No. 1, near Bright; the Kia Ora, on the Ovens river, at Eurobin; the Confidence, at Eurobin; the Ovens Junction, the Myrtle Queen, at Myrtleford; and the Guildford, on the Loddon; while in the Sandy creek region, where no great national damage has yet been done, it has to be noted that the leases of the Briseis company cover most of this very rich valley, down to Huon-lane. The board considers it nothing to the purpose that the owners of the lands are being compensated, possibly richly, nor does it attach much importance to the inclusion of re-soiling conditions in the leases, for the reason that the members are unanimous in the belief that no other forms of restoration avail in returning these lands to their pristine productiveness. If any system can be devised by which all dredging leases now in existence can be so curtailed in area as to eliminate from them all land of agricultural value, either present or potential, no delay should take place in putting it into execution; and this point it desires to accentuate beyond any other. It may be accepted as a fact, the board considers, that, so far as has been observed, all the lands, or very nearly so, which might be dredged without injury to the future of the state, have either been actually dredged, or are included in existing leases.

There are now lying at the Department of Mines, 61 applications, covering 11,525 acres of land, for dredging and sluicing purposes, of which it is proposed that 3880 acres shall be dredged, and the following instances are quoted as indicating the character of much of the country that is sought to be used for dredging

or sluicing: Ovens Valley. (Killawarra, 900 acres.) This land is situated near the Ovens and Murray rivers, and is of the general character of the Murray valley country, being of great productiveness. Murray Valley. (Corryong, 1200 acres.) This is notable grazing country, which will, with railway connections, if not meanwhile destroyed, become thickly populated. Murray Valley. (Surveyor's Creek, 1080 acres.) Characteristic grazing country of the Upper Murray. Loddon Valley. (Ravenswood, 450 acres.) This is a continuation of the Harcourt fruit producing country. Morra-bool Valley. (Morrisons', 2300 acres.) This is fair grazing country, with tracts of good agricultural land, within 23 miles of Ballarat.

"The board advises most decidedly against the continuance of bucket dredging on land suitable for agriculture. The board recognizes the wisdom of the Ministerial order of 1909, by which a maximum value of £3 per acre was placed on land which might be dredged. It thinks this maximum at most should be retained, and recommends that the provision be given force of law by enactment. In reference to valuable lands being included in existing leases, the board feels that, if these can be rescued from the dredge or sluicer, no reasonable effort should be spared to do so. Even if the policy of the non-issue of leases for land of £3 per acre and upward in value be permanently adopted, it is considered to be essential that the true value of any land applied for, and its potentialities, shall be ascertained, and this demands the assistance of an agricultural land expert valuer. This is recommended for observance in connection with all future applications for dredging leases.

Recommendations of Board

"The board cannot acquiesce in the contention that good land, after having been dredged, may be restored by the processes laid down by the Department of Mines. Even re-soiling does not apply where the depth of overburden is less than two feet. Yet two feet of soil in its natural state is frequently of great value, and always capable of producing crops. When dredged, it is lost absolutely. Nor can the board accept the view that where the overburden is over two feet, the results of 'advance stripping,' and depositing wet, from dredge buckets, on shingle heaps, are restoration. It is idle, in the opinion of the board, to contend that land so treated is not seriously injured permanently. By its general observance under covenant, the present condition of two feet of overburden and under might be eliminated from those relating to re-soiling, inasmuch as the material would be removed in dry condition in advance of dredging, and spread systematically over the rear shingle and silt. This system the board recommends for adoption in connection with all leases that may possibly be issued henceforth, and also with those which, after due investigation, it may be considered equitable to renew; and, further, should in any circumstances in the future, dredging leases be granted over areas possessing over two feet of overburden, at

least two feet in depth of that material shall be deposited 'dry' on properly leveled and prepared surfaces, or shingle and silt.

"Under no circumstances should permission be given for the disturbance, by dredging or sluicing, of the bed or banks of any river or principal stream and should any land be found of a less value than £3 per acre, which it may be desired to dredge, no lease boundary shall approach nearer to the bank of a stream than one chain, and that only such 'grips' for abstracting water for dredging operations from such river or creek shall be cut as shall, after inspection, be authorized by an officer of the Sludge Abatement Board."

The board advises against lessees being permitted to construct dams on streams, for flotation or other purposes; that in no case shall settling or precipitation dams be constructed across rivers or creeks, or than as represented by a line in cross-section of 4 horizontal to 1 vertical, from the bed of such river or creek, and that all such precipitating works shall be constructed above flood level, or, where that is found impracticable, the construction to be of a stable character, to designs to be approved by the Sludge Abatement Board, and carried out subject to that board's inspection, supervision, and direction. The present allowance of 800 gr. of earthy material per gallon of effluent water, whether from dredging or sluicing operations, is regarded as an excessive maximum, which, if availed of in practice to the full limit, would produce heavy discoloration and deposition in the streams which must ultimately receive it. A majority of the board, six members, proposes a reduction of this minimum to 100 gr. per gal., while a minority, numbering three, considers that the reduction should be from 800 gr. to 450 gr. Out of 278 cases in 52 instances, of dredging and sluicing, the rate of matter in suspense was under 100 gr., in 62 it was over the maximum of 800 gr. per gal. The report also recommends that all miners' right holdings for dredging and sluicing shall be brought under the control of the Department of Mines and the Sludge Abatement Board, as regards disposal of dredged or sluiced material, and effluent water, exactly as are the dredging and sluicing leased areas.

The Smuggler Union Air Lift

By WALTER L. REID

The accompanying figure illustrates the design of the air lifts which I have adopted in the Smuggler Union mills at Telluride. The advantages of this lift, which have been demonstrated by several months operation, are as follows:

1. It automatically takes the exact amount of air required at any moment. This is decidedly important, as our experience has shown that trouble may be caused from too large an air volume quite as frequently as from fluctuations in the quantity of pulp to be raised. Again, where several air lifts are being supplied by a compressor operating up to capacity, this

control serves to keep the air requirements for the several lifts more nearly uniform.

2. Owing to the check valve being placed near the outflow of the air line, there is practically no choking of the air line itself.

3. Should the lift pack full of sand and slime, while standing during a prolonged shut-down of the compressor, it can usually be started in a few minutes with no other attention than to turn on the high pressure water or solution line; this has been done after

the lift had been standing for four days filled with sand to the top of the intake box.

4. When necessary to renew any of the fittings that may wear, the section A can be quickly removed by taking out the bolts on the two flange unions.

The intake box provides an ideal place for screening the feed so that no chips or other debris are allowed to flow into the lift.

Leaching of Zinc Ore at the Afterthought Mine

By FRANK L. WILSON

The ore of the Afterthought mine, Ingot, California, contains so high a zinc content that ordinary smelting methods are not practicable. The ore is a complex 'black jack' averaging 14.3 to 15.6% zinc and 11.6% iron, the zinc at times reaching 30 to 40%. Most of the sulphide ore averages about 18.7% sulphur. This ore gave considerable trouble in smelting, because the zinc and barite caused clogging of the tap-hole and crusting over of the top of the charge. The zinc had to be in part carried away in the slag and matte, and in part was volatilized. When the plant of the Great Western Gold Co., as it was then known, was in operation during 1905, 1906, and 1907, the ore was smelted in a 150 by 42-in. blast-furnace designed by S. E. Bretherton. Mr. Bretherton devised the scheme of using hot blast and running the furnace with a low column of ore above the tuyeres and a hot top to overcome these difficulties. Results showed that 40.92% of the zinc entered the slag, 11.04% the matte, and 47.98% was volatilized. During a period of 5 months, in which the furnace was in operation 128 days, 2,046,031 lb. of zinc was volatilized, or an average of 16,000 lb. per 24 hours. No attempt was made at that time to save the zinc fume, because of financial difficulties.

The coke and supplies for the smelter and mine were hauled by wagon from Bella Vista, a distance of about 13 miles. This expense, added to the hauling of the matte produced back to Bella Vista, led to a complete shut-down of the plant in December 1907, at which time copper was at a low price. Development at the mine was continued intermittently and repair work kept up. In a report presented to the directors of the Company in 1911, there was shown to be over \$11,000,000 worth of ore developed. This ore will average at least 20 to 25% zinc, and large blocks will run as high as 30 to 45% zinc. During the interval of six years' inactivity, the exposed wood timbering at the smelter has had to be repaired. The iron fine-dust chamber has given some trouble also. From time to time the expensive machinery about the plant has had to be overhauled, for there have been continued hopes that operations would be resumed. In all, the plant has been fairly well preserved.

Afterthought ore was sent to several places and tested for zinc extraction and recovery. Of the many processes tried, the ammonia carbon-dioxide process was found to be the most proficient. David Mosher, of San Francisco, first suggested the use of ammonia and carbon dioxide in solution, as devised by Carl Schnabel. Mr. Mosher at that time was interested in the ammonia-cyanide process. I made a series of tests on zinc extraction from the Afterthought ore

with ammoniacal solutions in connection with my graduating thesis at the University of California. The results so clearly proved the value of the process that several patents were applied for, which have since been secured. As a result of these tests, it was decided to install this process on a commercial scale at the mine, and to work out the suggestions that had presented themselves in the preliminary tests on the Afterthought and other ores. A preliminary testing plant of 25 lb. capacity was erected and further checked the smaller tests.* No pressure was used, it being desired to see if the more expensive plant could be done away with. It was found, however, that with pressure the time and amount of solution is cut down to a minimum, which greatly offsets any extra expense in the initial cost of the plant. Using pressure, the ore is agitated, leached, and washed in 8 hours, and only 5 tons of solution to 1 ton of ore has to be treated for the recovery of the zinc, copper, and gases. A testing plant using pressure is now in use with a capacity of 50 lb. per 8 hours.

The ammoniacal solution is separated from the ore in a laboratory Kelly filter-press, and the solution then treated with scrap zinc or zinc dust for the removal of copper and any silver that might have passed into solution. This is again filtered, the cement copper being sold for pigment or thrown with the residue in to the matting furnace, and the clear solution is sent to a battery of stills, where the free ammonia and carbon dioxide are boiled off by the use of live steam and caught in properly constructed absorbers. The zinc precipitates as a granular and semi-flocculent white basic carbonate. This precipitate is filtered through a press and is either sold as the carbonate or calcined to oxide, which has been pronounced of excellent quality for paint body.

In July 1913 the stockholders, at a special meeting held in Indianapolis, decided to try, under the leadership of George L. Porter, to raise a bond-pool of \$250,000 to liquidate all debts, construct a 50-ton reduction plant at Ingot, and have a reserve fund for immediate operation expenses. Nearly all of this pool has been subscribed, and hopes are high for resumption of operations on a large commercial scale in the near future.

The Laloki mine, on the island of Papua or New Guinea, north of Australia, contains 145,000 tons of basic ore averaging about 4% copper and 2.25% gold above the 140-ft. level. An option held by the Great Fitzroy Mines, Ltd., has been exercised by Bewick, Moreing & Co., the general managers.

Accidental Discoveries of Mines

By G. L. SHELDON

Many years ago two prospectors were grubstaked by a saloon-keeper in a town not far from the present Coeur d'Alene district, Idaho. They were given a burro on which to pack their food and supplies. They returned for more grub several times. Finally, being discouraged and 'out of sorts,' they quarreled and divided up the outfit. One struck out down the gulch, the other, to whom the gun and burro fell, went to hunt his burro. He found him up on the side of the mountain standing upon the outcrop of what is today one of the largest dividend-paying mines of the district.

In the early days of the Granite Mountain mine, Montana, which has paid many millions in dividends, when the shaft was about 100 ft. deep, driving was being done from the bottom of the shaft. It was customary for the miners to drill and shoot a certain number of holes for a shift's work, and they were given a sufficient number of sticks of powder for the holes drilled. The ground was pretty tough, and as the shift-boss was an easy-going man, some of the miners would throw some of their powder through the cracks of the timbers near the bottom of the shaft, thus avoiding the drilling of one or two holes. One day one of the miners, the last one going up, threw a stick of powder, with a lighted fuse attached, in behind the timbers. The explosion was so terrific that it proved that many of the miners had been caching their powder there. The explosion opened up another parallel vein which was very rich.

A one-time partner of mine, in the early '70s, traveling on foot along the main trail from Red Mountain to Ironton, Colorado, sat down under a tree at the side of the trail to rest. Having a small prospector's pick in his hand, he broke a piece off the rock nearest to him, and this proved to be galena. An hour's prospecting on the mountainside disclosed the vein, although hundreds of good practical miners had passed over the trail without noticing the float. He took out \$20,000 worth of ore, and sold the claim for \$70,000.

At the Camp Bird claim, near Ouray, Colorado, the men doing the annual assessment work late in the fall cut some material in the drift that was different from the rock which they had been driving. On account of a heavy snowfall they were obliged to leave the property in haste, and forgot to take samples of the new material with them. Eventually this rock, which had been thrown on the dump, proved to be rich ore and led to the discovery of the now well known Camp Bird mine.

Years ago at Delamar's Trade Dollar mine, in Idaho, a new foreman examining a dump made before his arrival, noticed some strange material that had been thrown over the dump and found that it was rich sil-

ver ore. Not long afterward, for some trivial cause, the foreman was discharged, and later the owner himself ostensibly discovered this ore in the mine. He was ashamed to have it known that he had been throwing the ore over the dump.

The good luck of the wife of the original discoverer of the Enterprise mine, at Rico, Colorado, led to its discovery. In sinking a wet shaft, the owner had become heavily in debt, when his wife was fortunate enough to draw a \$4000 prize in the Louisiana lottery. She had the nerve to put it into the mine, receiving an undivided one-half interest. With this they were enabled to sink farther, and eventually opened a blanket vein which led to the discovery of the same vein on adjoining properties. After taking out a million, the Enterprise was sold for one and one-quarter million dollars.

The Tomboy mine, Telluride, Colorado, in its prospect days, was taken over by a hardware merchant, the surface indications being poor, for a debt of \$1200. This led to its development into a paying mine, and it was afterward sold to an English company for more than a million dollars. It is still paying dividends.

The Republic mine, Chihuahua, Mexico, was discovered by the wife of a peon, who was washing clothes in a creek. Her attention was attracted by some pretty stones; she took them home and her husband recognized them as rich silver ore. He found the vein a few hundred feet above the place where it crossed the creek, the vein being exposed in the cliffs for 200 ft. An American, who lived near, purchased a half interest for \$1500. After doing some development work and shipping some high-grade ore, they sold the property for \$150,000. The mine is paying dividends today.

It is claimed that the rich gold camp of San José de Gracia, Sinaloa, Mexico, was discovered by the Spaniards about 100 years ago. Having heard of gold in that section, they were investigating the district. Being out of meat and seeing an Indian hut and goat corral, with goats within, they rode up to buy some goats and noticed that the corral was made of gold-bearing quartz. Upon examination the rock was found to be rich in free gold. The vein was discovered nearby and a rich mine was opened which is still producing.

The calamine deposits of Leadville, Colorado, were for many years unrecognized by the best mining men of the country. Hundreds of tons of this ore was thrown on the dumps, until finally some one happened along who recognized the ore. This discovery led to the rejuvenation of the old camp. The same is true of the Potosi mine in southeastern Nevada, the eighth patented mine in the United States, worked by the Mormons in 1860 for lead. Until recent years no one knew what composed the immense deposits of grayish, sandy material. Finally, an engineer, who happened to be passing that way, saw the deposits and noticed that they consisted of calamine, containing 34% zinc.

Winter Dredging in Idaho

By JOHN H. MILES

Gold dredging in the winter has many disadvantages, and mining men may be interested in the following remarks, concerning the operation of the 18-cu. ft. boat built by the Yuba Construction Co. for the Boston & Idaho Gold Dredging Co., and now completing its third season's work. The dredge is at Idaho City, Idaho, and when it is noted that this place is near the 44th parallel and has an altitude of nearly a mile, it will be understood that its climate is somewhat different from that of the California fields.

There is very little trouble with ice forming on the pond until the temperature reaches 10° below zero, when ice begins to form in the corners. If the cut is narrow enough so that the boat can go from one side to the other in 6 or 8 hours, there is not much difficulty, as little ice will form in that length of time. But if the pond is over 700 ft. wide, it is impossible to carry a 10-ft. step and cross the pond in less than 16 hours. This gives ice time to form about one-half inch thick. As the boat moves across the pond it forces the ice into the corners, making a solid mass three to four feet under water and two to three feet above water. It is often necessary to dynamite to loosen the ice so that the boat can dig the corners. This trouble increases as the thermometer drops, and when 20 to 24° below is reached it is necessary to stop digging and move the boat across the pond as fast as possible, keeping the pumps, bucket line, stacker, and screen running. If the trip can be made in about 40 minutes, the water is kept so agitated that ice will not form more than one-fourth inch thick during the boat's journey. All the time large cakes of ice are taken up by the bucket line and carried through the boat to the tailing pile and this helps to clear the pond, especially in the corners.

Although it sometimes gets colder than this for a few hours, the cold snaps seldom average worse than 24° below, and this usually lasts only a couple of days. The ground freezes about three feet deep and caves off in great slabs which have to be broken up by the

buckets. Some difficulty is experienced in handling these chunks in the hopper and on the conveyor belt.

The snow is a serious handicap in moving the lines, although the system used gets around this trouble very well. Two 1½-in. cables are stretched, one on each side of the boat and running 3000 ft. ahead, and anchored at 200-ft. intervals. This is equivalent to a continuous dead man on each side. All side lines are moved every 24 hours, and by so doing are kept at the proper angle with the boat to give the best results. With the help of four horses and two men, all side lines can be moved ahead in about two hours without losing any running time. After a fresh fall of snow the teams break new trails for line changing. One team, used for emergency night work, is kept in a portable stable which is moved along as the boat advances. The amount of snowfall has not exceeded four feet in the past three years.

Another problem is to heat the boat to a degree of comfort for the men and keep the stacker rollers and drum free from ice without using too much fuel. Wood is the only fuel available, at a cost of \$4 per cord; five cords per day are used in the coldest weather. The dredge boiler is 80 hp. and is connected to over one mile of 2-in. heating pipe. There are also four home-made electric heaters connected in series across 2200 volts. These are used alone until the thermometer reaches the zero mark. The capacity of the four heaters is 44 kw. The frames and the heavy screens which guard the heaters are thoroughly grounded; the outfit has proved a useful feature for the earlier part of the cold season. The stacker needs heat as soon as the temperature is at the freezing point. From 32° above down to 10° below, the stacker and winch room are supplied from a 2-in. auxiliary line. As the weather gets colder, steam is turned into the 4-in. main line that heats the boat in general. The steam pipes under the tables are not used, except on clean-up days, until 15° is reached. The ice that forms on the tail sluices, stacker, and ladder is broken

off every other day. Ice troubles in all have not caused more than a total of 4 days lost running time to date, though the dredge is now in its third winter.

This boat is now equipped with 18-cu. ft. buckets in place of the 15-cu. ft. buckets originally furnished. The November yardage was 385,196, averaging 683 yd. per hour; the December yardage was 403,144, or 703 yd. per hour. Yardage is measured under the same system used at Natoma, California, one-third slope being deducted for sides. The crew consists of 9 men, as follows: 3 winchmen at 56c. per hour; 3 oilers at 50c.; 1 deck-hand, night only, 10 hours, at 40c.; 1 teamster and 1 shore-man, each 10 hours, at 32½c. This is probably the only large dredge operating with

ICE ON DIGGING LADDER.

only one oiler on a shift. The boat is equipped with inter-communicating telephones. There is an automatic stop for stacker and screen that is tripped whenever the stacker belt gets overloaded. This is necessary on account of the large frozen chunks that lodge between the side boards of the conveyor.

The tables have a combined area of 6000 sq. ft., and to wash the maximum capacity it is necessary to use three 14-in. pumps handling nearly 20,000 gal. per minute. The main drive belt is now 36-in. leather, double ply. Leather belts are used on the screen and stacker motors. All other belts are rubber. The conveyor belt is speeded up to 465 ft. per minute—about 100 ft. faster than usual practice.

It is of interest that the November and December yardage of this boat, already noted, approaches a total of a round million tons.

Seven Edwards roasting furnaces are working at the central treatment plant of the Ashanti Goldfields mines, West Africa.

Mt. Rainier, Washington, is 14,408 ft. high.

Standardization of Terms

By WILL H. COGHILL

The Chemical, Metallurgical, and Mining Society of South Africa has recently adopted and published certain terms and definitions with a view to establishing uniformity in the use of technical terms, and we might emulate our South African friends to our profit.

One fault is the continual use of certain terms that have been picked up from chemistry. These have been borrowed from the chemist and used in such a ruthless manner in metallurgy and geology that our creditor is now advocating that we be a little more consistent and thus avoid

foreclosure proceedings.

The term neutral is much used by metallurgists. The student in chemistry learns that neutral means having the properties neither of an acid nor a base. But this is only his first lesson. When he gets about half way through his 'Principles of Copper Smelting,' he learns that atmosphere can also be neutral, because a neutral atmosphere is one that is neither oxidizing nor strongly reducing.

If one is inclined to browse among the English authors, he will find,

on p. 296 of Roberts-Austin's 'Introduction to Metallurgy,' that " $2\text{RO} \cdot \text{SiO}_2$ is the neutral silicate of the metallurgists."

I am unable to glean one bit from this statement, but was taught in school that a neutral slag was a very fluid corroding slag; more fluid than if the silica content were either increased or decreased. However, when it came to furnace linings, neutral bobbed up again, this time the antithesis of the neutral slag, in the form of a chromite brick which would neither fuse nor corrode. After all, it is not so strange that it is difficult to correlate neutral, for we read in Hofman, that: "The so-called neutral ore is of different composition in different districts, even differing sometimes in the same district."

The silicate degree is confusing. In chemistry the student becomes more or less familiar with ortho, meta, di, and tri, but when he gets to metallurgy, some one must sugar-coat mono-silicate, bisilicate, and trisilicate, and administer them to the patient. When the coating dissolves, he finds that, while in chemistry $4\text{H}_2\text{O} \cdot 3\text{SiO}_2$ was trisilicic acid, in metallurgy $4\text{RO} \cdot 3\text{SiO}_2$ is a sesquisilicate, because the ratio of oxygen in the

base to oxygen in the acid is 2 to 3. Needless to say, the pills fail and the instructor is obliged to have the class learn to sing. Ratio of the oxygen in the base to the oxygen in acid, sub, mono, bi, tri, to the tune of Yale Boola for weeks before it soaks in.

Acid and Basic

The student may run the gauntlet in metallurgy and geology until he gets to acid and basic, but if he sticks through that ordeal there is hope that he will fight it out to the end. Maybe the complexness of the subject lends attraction, for young men are looking for worlds to conquer and pass up the easy subjects because anyone can learn them and competition for positions in such lines would be too severe. In chemistry the student learns that the radical, OH, in the formula of a salt means a basic salt and in mineralogy he naturally correlates calamine, $Zn_2(OH)_2SiO_3$ as a basic silicate and makes a test for H_2O . He begins to feel, however, that he has lost the scent after he has searched a whole page of analyses of iron blast-furnace slags, all of which are said to be basic and finds no column, 'per cent H_2O .' It begins to seem like a true paradox when his assay report on ores that contained a large amount of acid trisilicate fails to check the records in the office, within the proverbial four-hundredth, because his slag was too basic: when magnesia (MgO) is recommended as a basic refractory material, when he takes a trip to the lead refinery where he sees great stacks of base lead bullion, so called because it contains gold, silver, copper, iron, bismuth, antimony, arsenic, etc., and last of all, but not least, when his geology instructor talks at length about the composition of basic rock and does not mention his old friend 'OH', he discovers that he has made a mistake by beginning with basic instead of acid, because acid begins with a and basic with b. Thereupon, in Kemp, he finds that acid is a descriptive term applied to those igneous rocks that contain more than 65% SiO_2 , but begins to lose courage when he notes the apology, that: "The statement that acid rocks are least fusible often puzzles a student who is familiar with blast-furnace practice and the composition of slags, in which the most silicious are regarded as the most fusible. . . ." Kemp's definition does not make much of an impression, because apologies by a superior are inexorable in the eyes of the student. He then finds that borax is classed as an acid flux. Procuring a piece of borax and litmus paper, he moistens the borax and applies the litmus and, behold, borax is basic. A splendid bit of sarcasm it was, when a professor of biology asked a candidate for a master's degree in geology if he could distinguish between acid and basic rocks, with litmus paper.

Why Not Speak Correctly?

There may be those who will say: What is the difference whether the furnace-man calls his slag acid or silicious, basic, or nonsilicious, so long as he can run the furnace at a profit? Such an argument is of about the same weight as the time-worn statement that one

man can see as far into the ground as another. It can only be said in reply that if one wishes to use terms loosely, there is no penalty fixed by law.

It must be admitted that the terms cited do make an awful jumble for the veteran, to say nothing of the recruits. They were borrowed from the chemist when chemistry was a mere system and now that chemistry is fast developing into a science and acid and base are defined in terms of hydrogen and hydroxyl ions, they should be dropped or used just as the chemist does.

What Does Neutral Mean?

On page 23 of Hixon's 'Lead and Copper Smelting,' he speaks of a slag as ". . . near enough to a neutral slag to flow freely. . . ." Now of all things on earth that Hixon does not mean, it is neutral, for his neutral slag would rapidly corrode a basic lining and thus act as an acid slag or corrode an acid lining and thus act as a base. This is absolutely contradictory to the definition of neutral. He means a eutectic slag. Eutectic is an every-day word with metallographers. It means: "Of maximum fusibility: said of an alloy or mixture which has the lowest melting point which is possible to obtain by the given components." It is ready to dissolve more of any of its components when the temperature is elevated, and remain fluid. This is a description of the so-called neutral slag. (By the law of probabilities, it would not happen once in a million times.) Therefore, I will say eutectic instead of neutral slags. When neutral atmosphere and neutral refractory material is spoken of, inert, "not affecting other substances when brought into contact with them," is what is meant. When we say acid, we mean silicious. When we say basic we mean nonsilicious. Why not say what we mean? A silicious slag or rock is one in which the flowing temperature would be reduced by decreasing the silica content; a non-silicious slag or rock is one in which the flowing-temperature would be reduced by increasing the silica content. Flowing-temperature, not formation-temperature, is the theme with Peters in his discussion of slags, and Kemp, immediately following his definition, discusses the flow of the acid and basic magma. We then have, silicious, non-silicious, and inert refractory material. The neutral ores can be called self-fluxing and borax can be said to act as a silicious flux. Instead of saying ratio of oxygen in the base to oxygen in the acid, would it not be better to say, ratio of oxygen in the metallic oxide to oxygen in the silica?

A shortage of firewood at the Ashanti Goldfields mines, West Africa, has resulted in the installation of suction-gas engines for driving generators and an air-compressor. The plant now consists of three gas-electric generator sets, and one air-compressor set with two 700-hp. gas producers, and one 300-hp. producer. One generator set will always be used as a standby. It is expected that, early in 1914 all of the motors for the central treatment plant will be working, before the annual firewood troubles start.

Mining and Washing Brown Hematite Ores

By W. R. DODGE

The total production of crude iron ores for the year 1912 was 63,859,728 short tons. Of this amount, 3% or nearly 2,000,000 tons was brown hematite, the mining of which in Virginia, Tennessee, Georgia, and Alabama forms an important industry. The deposits are widely distributed throughout the Appalachian system from Alabama to eastern Canada, there being also important deposits in Texas, Iowa, and Colorado. The composition of the ore in its pure state is $\text{Fe}_2\text{O}_3(\text{OH})_6$ and contains: iron, 59.92%; oxygen, 25.64%; and water, 14.44 per cent.

Many hypotheses have been advanced as to the origin of these deposits, the conditions in each region varying somewhat; but the general opinion is that through the agency of surface waters, which have leached through and drained from a large area made up of porous ferruginous soils, the iron has been dissolved and kept in solution. This solution has collected in basins or cavities in the impervious soil or strata, and the dissolved iron has been precipitated from the solution either by lime or potash, according as to whether the basin or cavity was composed of limestone or slate. These rocks have in turn been decomposed and a residue of clay has been left by their alteration.

Occurrence and Testing of Ores

The ore takes the form of geodes or 'pots,' pipes, stalactitic masses, cellular aggregates, and smaller lumps and grains, from which the barren clays and ocores are removed by washing. The ore is but a fraction of the material mined. It occurs in irregular streaks throughout the clays, also often widely distributed over the surface in lumps and nodules forming a gossan. The mining must of necessity be by stripping and by open-cuts, as underground mining would present great difficulties and the cost be excessive.

An estimate of the value and extent of these deposits is usually made by drilling or by sinking test pits; the latter being preferable, as they are cheaply sunk in the soft decomposed clayey soil and render a visible examination possible. The pits are generally $3\frac{1}{2}$ ft. diameter and 30 to 60 ft. deep. They are sunk at regular intervals, corresponding to the checker-board system of squares, the sides of each square being 200 ft. A pit is sunk at the intersection of the lines forming each square. The dirt removed from these pits is carefully sampled, the grains and lumps are recovered by washing the clay, and the tons per cubic yard are calculated.

Ideal conditions for mining with steam-shovels exist where the deposit lies in a low hill and close to the surface. The latter condition precludes the necessity of the expense of stripping the overburden. This

situation on a hillside enables the ground to be worked in benches or terraces, and good drainage is obtained, which is extremely important where the soil is of clay.

Steam-Shovel Mining

These banks or terraces are so arranged as to give a cutting face of 10 to 20 ft. vertically, with a base wide enough to hold comfortably the steam-shovel and the narrow-gage railroad track serving it, the width being usually 25 to 30 ft. These banks, one below the other, are cut simultaneously. All obstructions ahead of the shovels, such as trees, underbrush, and boulders, must be removed. A large tree 3 ft. diameter and 60 to 80 ft. high is felled, sawn into logs, and the stump dynamited by two men in ten hours. The brush is piled into heaps and burned. The boulders are shattered with dynamite. The steam-shovels for this work must have maximum digging capacities, yet be light of weight to allow of quick change of position over a rough grade. The Vulcan shovel is a favorite for this work. The 35-ton 1-yd. dipper size has a capacity of 500 to 700 yd. per 10 hours. Each shovel has a crew of 5 men, and consumes $2\frac{1}{2}$ to 3 tons of coal per day.

Narrow-gage (36-in.) steam trains, made up of locomotive and five 3-yd. cars, transport the material mined by the shovels to the washer. The locomotives are of the saddle-tank type, ranging in weight from 10 to 18 tons, according to the load requirements. They will easily handle a 15 to 18-yd. train up a 4% grade. The average speed over a good track is 8 to 10 miles per hour. A 12-ton locomotive consumes one ton of coal per 10 hours, and has a crew consisting of an engineer and a fireman. The tram cars for carrying the ore are of the high-frame, wooden body, side-dumping type. The body is 8 ft. long, 6 ft. wide, and 18 to 20 in. deep. They hold three yards. The body is hinged along its longitudinal axis, these hinges resting on the tops of A-shaped steel trusses carried on the trucks. The body is held in balance by means of four chains, two on each side. The car is emptied by releasing the chains opposite the side it is wished to dump, whereby the body is overbalanced and the load is allowed to fall out. The side doors are supported independently of the body and do not rotate with it, thereby allowing the dirt to slide out underneath them. Three men are required to dump these cars.

Construction of Tracks

The rails for the permanent main track are usually 40 to 56 lb. per yard. Oak ties are placed at 2-ft. intervals. In the headings, along the banks that are being mined by the shovels, the tracks must be constantly shifted in order to serve the shovels as they change their positions. The rails here are lighter, 30

to 36 lb. per yard. Whole sections of this track, 100 to 150 ft. in length all intact with ties, etc., are moved at one time by the track gang of eight to twelve men. No preliminary grading is done, other than a rough evening up of the ground. The track is strung out and the low places under the ties filled in with blocks or logs. Water-pipe lines are laid by the side of the track to serve the shovels.

A hillside position is chosen for the washer in order to secure sufficient elevation. The total height required from the standard-gage railroad track beneath the shipping bins to the crude-ore bins at the top of the plant varies from 40 to 60 ft. The crude ore is received at the top of the plant in a V-shaped hopper, 5 to 6 ft. wide across the top, 2 to 3 ft. deep at its upper end, and 50 to 60 ft. long, or long enough to receive the loads of a 5-car train of dirt. This hopper has a false bottom of 65-lb. rails, placed bottom side up, with 4-in. spaces between them, thus forming a grizzly. This grizzly is set on a grade of $1\frac{1}{2}$ to 2 in. to the foot, slanting toward the washer. The function of this grizzly is to support the ore in a mass above the true bottom, two feet below it, and to enable the large lumps and boulders to be broken. Beneath this grizzly is the true bottom of the hopper, which is a cast iron lined flume set on a grade of $2\frac{1}{2}$ in. to the foot. This flume is $1\frac{1}{2}$ ft. wide and the liners are semi-circular in section, 1 in. thick and 4 ft. long. Water is admitted at the upper end of the flume and flushes away the dirt as it is fed down through the grizzly by men with long picks.

Washing and Screening

The water and ore enters a revolving trommel with 2-in. round holes. This trommel is cone-shaped and mounted on tires, which are in turn carried on friction rollers and driven by them. The trommel, besides removing the oversize, also acts as a distributor of pulp to the log-washer beneath it. The oversize, consisting of lump ore with impurities as mud and clay balls, is washed by spray pipes and discharged upon a pan-conveyor picking belt. Here the impurities are removed and the clean ore is sent to the ore-bins for shipment.

The undersize from the trommel passes through the log-washer. This consists of two wooden or steel logs, octagonal in section, $1\frac{1}{2}$ ft. diam. across flats, and 20 to 30 ft. long. The logs are mounted on gudgeons and have a pitch of 1 in. per foot. They work in a rectangular flat bottomed box 7 ft. 4 in. wide, 4 ft. deep at their lower end, and 2 ft. deep at the upper end, according to the length of the logs. The lower gudgeons are enclosed in grit-proof step bearings under water. To the upper gudgeons, which are out of water and work in journals, is fastened the driving gear. To the logs are bolted blades or paddles of hard steel, 9 to 10 in. long, $5\frac{1}{4}$ in. wide, and $1\frac{1}{4}$ in. thick, in such a manner as to form an interrupted screw conveyor. The undersides of the logs rotate toward each other.

The crude ore pulp is fed to the logs near their lower end, while clean water is admitted at the upper end. The pulp is in constant agitation, the clay and mud being disintegrated and washed out as slime at the sides of the box. The ore settles to the bottom and is worked by the action of the logs to the upper or discharge end. The speed of the logs is 12 to 15 revolutions per minute.

Treating Fine Material

The discharged material still retains impurities as slime, clay, and fine sand. It is further cleansed by being washed in a double-shell perforated screen. The outer dimensions of the screen are: length, 8 ft.; diameter, 42 in. The driving gear and the tires are attached at the extreme ends. The tires, in turn, rest on rollers. The outer shell is of No. 18 steel plate with perforations $\frac{1}{16}$ in. by $\frac{1}{2}$ in. The inner shell is 32 in. diameter and of $\frac{1}{4}$ in. steel plate with perforations $\frac{3}{8}$ in. by $1\frac{1}{4}$ in. This inner shell is intended to receive the major part of the wear and thus protect the outer shell. There being no spider arms to this screen, spray pipes are extended into it to wash adhering mud and sand from the ore.

The product from this screen is discharged upon a pan conveyor which serves as a picking belt. The impurities, such as gravel and clay balls are here removed and the clean ore passes to the shipping bins. The pan conveyor is made up of a series of pans, each pan being of $\frac{1}{8}$ in. steel plate, 15 to 18 in. long, 23 in. wide, with sides $2\frac{1}{2}$ in. high, bent up at right angles. The rear end of each pan has a 1-in. angle iron riveted to it to prevent material from slipping back when the conveyor is inclined at a steep angle. The next pan rests on this angle iron. These pans are carried on links, two to each pan. The links are of the same length as the pans and are connected by a steel pin which extends across the full width of each pan. The head and foot of the conveyor are carried on smooth, flanged friction rollers. Between these at 4-ft. intervals are 12-in. rollers which give additional support for the links passing over them. The washed ore carried by this conveyor is discharged into the shipping bin, from which standard-gage railroad cars are loaded directly beneath.

Capacity of Plant

A standard MacLanahan-Stone washer, as above described, having four logs, will wash 1000 to 1500 yd. of dirt in 10 hours. It requires 1200 to 1500 gal. of water per minute and 75 hp. to operate. The ratio of crude ore mined by the shovels to the washed ore ranges at several of the mines from 3 to 1, to 12 to 1. A general average is 5 to 1.

The sludge or slime discharged from the washer is carried by flumes to the sludge pond, which covers a tract of 25 to 50 acres. These ponds are usually formed artificially by enclosing some low basin with embankments or levees 10 to 15 ft. high. They are built higher as the pond fills with sludge. Approxi-

mately 50% of the water in the slime settles out and is decanted off for re-use.

Pumping of the water is one of the most important items in ore washing. One plant using a duplex, double-acting, compound steam pump with 12-in. suction and 10-in. discharge, pumps 1000 gal. per minute through a $\frac{1}{2}$ -mile pipe to an elevation of 60 ft., at a cost of $4\frac{1}{2}$ c. per 1000 gal. A neighboring plant with a new installation of steam turbines direct connected to rotary pumps, furnishing 3900 gal. per minute, expects a lower cost than this.

Low costs in the mining and washing of brown ores depend on good weather conditions, uniformity of the ore deposit, a plentiful supply of water, and a small amount of stripping of overburden. A well managed property under the above conditions, and where the ratio of the crude ore or 'dirt' to washed ore is not greater than 6 to 1, can produce ore containing 50% iron for 50 to 75c. per ton.

General Rules for Safety*

1. Where gasoline is used for lighting steam-shovel and churn or well drill operations, safety cans are provided and must be used by employees for conveying and handling the limited supply allowed for each shift. The use of other than the approved safety, non-explosive cans for gasoline or other inflammable liquids is positively prohibited.

2. In the use of calcium carbide and acetylene gas machines, for lighting steam-shovel and all mine operations, the transportation and storage of the calcium carbide and the care of all equipment, generators, charging apparatus, and other details must be under the supervision of employees instructed and informed in the care and attendance of same.

3. Employees whose duties are prescribed by the above rule must always observe regular time, during daylight hours only, for attending to and charging all apparatus. Carbide charges must be sufficient to furnish gas continuously for the maximum lighting period to all burners installed, and generators must be of sufficient capacity to avoid recharging at night.

4. In the case of calcium carbide lights, all employees must observe the following cautions: (a) Never open or recharge a light in the presence of an open flame; (b) never test the generator or piping for leaks with a flame; (c) never apply flame to an outlet from which the burner has been removed; (d) never use a lighted match, lamp, candle, lantern, or open light near the machine.

5. Operators and employees of churn-drills or well-boring machines must not attempt to oil, wipe, or repair inaccessible parts while machine is running. Stop the machine before oiling parts that have to be reached by thrusting arm through wheels or between belts and pulleys.

6. Mechanics, shop employees, and repairmen are

*From the book of 'Rules and Regulations' of the Nevada Consolidated Copper Company.

instructed: (a) Not to strike highly tempered steel with a hammer or other metal object. Use a piece of wood or brass placed against it for hammer to strike; (b) never to shift a moving belt by hand. This rule applies to and must be observed by all employees on drills and other belt-driven machines or machinery; (c) not to wear loose or baggy clothing. Jumpers tucked inside of overalls might prevent clothing from being caught in machinery.

7. Employees are instructed, and it is hereby made part of the duty of every employee, to help protect and maintain equipment in safe condition.

8. Defective equipment, or impaired or damaged hand tools, must not be used. Employees must return worn or defective tools to their foremen, who will furnish them with tools in good condition and repair.

9. Old planks or boards with nails protruding must not be thrown aside to lay around tracks or yards. Blood poisoning and the loss of a leg may result from stepping on a rusty nail. For their own and their fellow-workmen's protection, employees are urged to take an interest in this too frequent cause of injury. When an old plank or piece of board with upturned nail is found, either bend the nail down or call it to attention of foreman, who will have it removed.

10. Employees who are careless of the safety of themselves or others will be discharged and dismissed from the service of the Company.

11. The use of intoxicants by employees while on duty is prohibited. Their use, or the frequenting of places where they are sold, is sufficient cause for dismissal. Employees are required to report any fellow-workman who is intoxicated while on duty.

12. Violation of, or the refusal to obey any of these rules, or of any special instructions not in conflict herewith and issued by proper authority, will be deemed sufficient cause for prompt dismissal.

Ore Treatment at the Camp Bird Mill

During the year ended June 30, 1913, the following results were obtained:

| | |
|-------------------------|---------|
| Ore treated, tons | 30,012 |
| Metal content: | |
| Gold, ounces | 0.958 |
| Silver, ounces | 3.830 |
| Lead, per cent | 1.420 |
| Copper, per cent | 0.217 |
| Value per ton | \$22.51 |
| Total value | 675,630 |
| Net recovery | 597,239 |

Of the total value extracted, there was obtained by amalgamation 49.28%, concentration 43.91%, and cyanidation 6.81%; of which gold constitutes 85.74%, silver 9.92, lead 2.33, and copper 2.01 per cent.

The Komata Reefs mine, New Zealand, has been shut down. During the past 16 years it produced gold and silver worth \$2,016,000. Of this, \$86,400 was from the sealing of plates, equal to an absorption of about 2.3 per cent.

Precipitation and Clean-Up at the Lake View Mill

By J. P. CADDY

*This plant treats sulpho-telluride ores from the Lake View & Star mines, Kalgoorlie, by wet crushing with stamps, Freeman pans, Wilfley tables, tube-mills, agitation with bromo-cyanide, and filter-pressing at the rate of 18,000 tons per month. Concentrate is roasted, ground in pans, agitated, and filter-pressed.

All cyanide solutions go to the same sumps, are pumped through two classifiers to a gold-solution tank, after passing a 3-in. Kennedy meter. From this reading and the value of the solutions, the amount of gold in the zinc-boxes can be closely estimated. There are 11 zinc-boxes containing 12 compartments each, only eight being filled with shaving. The capacity of each box is 23 cu. ft., one cubic foot of zinc weighing 12 pounds. About 75 tons of solution flows through each box daily, or 3.26 tons per cubic foot of zinc. The solution is worth \$2.88 to \$3.36 per ton, contains 0.06% KCN, with no protective alkalinity. The boxes are dressed three times and cleaned-up twice a month. New zinc is packed in the lower compartments after being dipped in a solution of lead acetate. Taking a solution entering the boxes worth \$3.06 per ton, the value after No. 2, 4, 6, and 8 compartments is 42 to 53c., 28c., 12c., and 3.6c. per ton. Zinc consumption averages 3500 lb. per month.

Clean-up apparatus consists of a washing tub 30 by 42 by 144 in., with sloping sides and bottom, fitted with 10 and 20-mesh screens; a lead-lined acid tub 6 ft. diameter and 2 ft. deep with sloping bottom to a 3-in. cock; Dehne lead-lined centre-filling filter-press of 12 frames, filled by a pressure tank; three cast iron roasting muffles, 12 by 20 by 53 in., with 1¾-in. bottoms; a tilting furnace to take a No. 9 Morgan crucible; two well furnaces to hold a No. 150 and No. 60 crucible, respectively, and two cast-iron amalgam retorts 7 by 15 by 42 in., each holding three cast iron trays, 4 by 8 by 12 in. The clean-up of the zinc-boxes is similar to the usual Kalgoorlie practice, the total time taken from starting on the boxes to getting bars ready for the bank is only 18 hours. Six men are employed. Only the short zinc under the 20-mesh screen is treated with sulphuric acid, the monthly consumption being 1100 lb. Cakes of gold slime from the press are roasted for 1½ hr., then fluxed for the tilting furnace. This furnace receives the first charge about 4½ hr. after starting the first clean-up, and the last of the gold slime is ready for roasting 10 hr. after starting. Fluxes are borax, 50%, and sand, 10 to 15%. The No. 150 crucible is sometimes used for melting the fluxed slime. The No. 60 is for making bars of 700 oz. each. Amalgam collected in the mill is also retorted and melted during the clean-up. A month's yield will be 1220 lb. of roasted slime, giving 4200 oz.

*Abstract from the *Monthly Journal* of the Chamber of Mines of Western Australia.

bullion, 830 fine in gold, 115 in silver, and 55 base. The amalgam yields 1500 oz. bullion, that from the concentrate being 975 in gold, 17 silver, and 8 base.

Geological Notes on Port Arthur and Vicinity

By WARREN D. SMITH

The extreme lower end of the Liaotung peninsula is studded with numerous treeless hills, having generally rounded tops and which are of moderate height. The famous 203-Metre hill is one of the highest in the immediate vicinity of Port Arthur. The small streams draining the country are in wide, almost flat-bottomed, valleys. The lower end of the main stream emptying into the harbor of Port Arthur is drowned in its lower portion; in fact, the harbor itself is nothing more than a submerged portion of this stream and of one or two of its former tributaries. The harbor is silting up at the present time, and apparently at a rapid rate. In a word, the topography has reached maturity, and late maturity at that. The absolute lack of forests will only hasten senility. In the vicinity of Port Arthur the Japanese authorities have begun to reforest the hills with Scotch pine. It may be that the experiment will be successful and that erosion will be checked in this locality.

As far as I could see from my extremely casual survey of the country during the few short hours' leave from the ship, the dominant rock in the district seemed to be quartzite, bedded and tipped at various angles, having some lenses and veins of pure quartz. On Pompelly's map of China* the lower portion of Liaotung peninsula is colored to indicate Devonian limestone. It is possible that this limestone has been metamorphosed into a highly silicious rock and resembles quartzite. In places there may be conglomerate overlying it consisting of pebbles of this formation, for specimens of it are to be seen in the military museum in Port Arthur. Both these formations are exceedingly hard. According to the Japanese authorities, their tunnels advanced during the siege only 50 centimetres per day. The formation is intersected in all directions by fractures and joints, and therefore should be more easily excavated by persons trained in practical mining. One reason why greater headway was not made by the Japanese military engineers was undoubtedly due to the fact that they could not use powder or dynamite at the time through fear of giving the Russians an idea where they were working. Quartzite being simply metamorphosed sandstone, and hence having a high percentage of silica, would afford little or no soil, and this seems to be true here. Such country should not be expected to afford much sustenance for troops.

Port Arthur affords a striking example of the bearing of geology upon human affairs.

*'Geologic Researches in China, Mongolia, and Japan.' R. Pompelly, Smithsonian Contributions to Knowledge, 1866.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Underestimating the Cost of Milling Plants

The Editor:

Sir—The planning and designing of ore-treatment mills has been the subject of several articles, very much to the point, during the last year in the *Mining and Scientific Press*, especially those of Sydney Additon.* On account of the importance of this subject to the mining industry, I trust that you will consider a further discussion of it is warranted.

The failure of mills to do what is expected of them is one of the reasons why investors are shy of the mining field. Everyone who reads this can call to his mind examples of rusting mills. The man who is not technically acquainted with mining and metallurgy often considers that this is one of the inherent risks of mining. He thinks that the success of a mill is a matter of chance. If you are lucky, you get a mill which treats your ore successfully. There is enough of the speculative element in the finding of ore, without introducing any in its treatment. It is a matter of much importance to the man who makes his living by mining to remove as much as possible of this risk.

There are two kinds of failures in mills, though differing mainly in degree. The one kind is the mill which is so poorly adapted to the treatment of its particular ore, and the return from the mill is so much less than the cost of operating it, that it is shut down in a very short time. The valuable metals go down the creek instead of into concentrate or bullion. The unlucky owners decide the ore is refractory, they have spent all their available capital, and the property is shut down. This kind of a failure is of course conspicuous, and is the usual kind thought of when the subject is mentioned.

The other kind of failure is the one in which the profits from the mill are not as large as they would be if the mill were properly designed. The returns, however, are still more than the cost of production, and the mill continues to operate. Now unless some one with an investigating turn of mind is connected with this mill at some time or other, the loss of profits may never be detected. If it is detected, some of the machinery may be thrown on the junk pile, to make room for equipment better adapted, or additional apparatus may be added and alterations made to adapt the plant to the scheme of treatment. In either case the profits will generally not be as large as if it were planned correctly in the first place. There is both the loss of money in the scrapped material and the

alterations made, and also that which is more important, as it is cumulative, the loss due to a higher working cost in the poorly planned mill. A mill whose flow-sheet has been juggled around a few times generally costs more to operate than it should.

The first type of failure is gradually becoming rarer, though even now I can recall three or four of this class in the last couple of years in the Northwest. Of the other class, we have no means of knowing the number. From the experience of every metallurgist, however, it is safe to say they are still with us. As long as mills continue to be planned from machinery catalogues, and by engineers whose specialty is mining and not milling, so long will such mills continue to operate at a loss to their owners. The remedy, as Mr. Additon points out, is the design of the mill by a metallurgist, the same metallurgist who conducted the testing of the ore, which is essential to a correct design.

The testing of the ore comes first, and is the foundation on which the correct design must rest. It is also the part of the planning which is often neglected, or not done in a thorough enough manner. In the first place, an ore test must be made on actual milling machinery to give results which can be duplicated later on in the mill. It must be made on a sufficient quantity of ore, so that errors are minimized as much as possible. I believe that, too often still, small tests are relied upon for information on which to base mill design. It is a well known fact that the old bottle amalgamation test, the pan concentration test, and others, are inaccurate. When such tests are relied on for a test of a combination of processes, or to get a comparison between different combinations, the results are little short of worthless.

It is just in this matter of the comparison of different combinations of processes that the thorough test is most valuable, and also where it is less used than it should be. For instance, a mill is planned for an orebody. A property nearby with what seems to be similar ore, is treating by amalgamation, fine grinding, and agitation in cyanide solution. As a matter of precaution, therefore, a test is made of the ore by the same method. This test shows a fair margin between recovery and operating costs. It is accordingly selected as the right process, and a mill designed to fit. But in such a case as this there should have been a comparison between the following combinations: amalgamation, fine grinding, and agitation (the one chosen); amalgamation, concentration, fine grinding, and agitation; amalgamation, classifying into sand and slime, and leaching sand and agitating slime, with and without concentration. Perhaps cyaniding alone, leaving out amalgamation, should have been tried, and to make the test complete, several variations of the above should have been tested. When the results of each of these tests had been tabulated and compared, the best process could then have been wisely chosen.

There have been a number of examples recently of

*See *Mining and Scientific Press*, July 19, 1913, et seq.

mills changing their scheme of treatment. Some that have been concentrating before cyaniding have rejected their concentrators, and thrown their work on the cyanide plant. Others have dispensed with fine grinding and now agitate only the natural slime, leaching the sand. Others have abandoned amalgamation, or have added it. All of these changes are expensive, and in many cases could have been prevented had a complete comparison been made at first of the different combinations of processes which were possibilities in the treatment of the ore in question. Until the importance of a thorough testing of the possibilities of treatment of an ore is realized, and the possibilities are thoroughly compared by proper testing, so long will mills continue to operate at an unnecessarily high cost, or to send to the tailing dump metal which might otherwise have been turned into profits.

I. F. LAUCKS.

What Is the Matter With Prospecting?

The Editor:

Sir—I have been reading the symposium on the lack of prospecting in the last few issues of the *Press*, and I think that most of the contributors have overlooked the most important feature in the whole matter, and that is the class of labor at present employed in the mines. Fifteen years ago you could make a shift boss out of practically any man in the mine. Today go into a stope of any the mines in the larger districts and ask the first man you meet a question about the mine, and two-thirds of the time you will be greeted with a blank expression and a shake of the head. Go up to the shaft when the shift is going to work or step into the office of the labor agent and listen to the inquiries of 'Catch a job dis morn?' Then try to imagine these men as prospectors. To these men a steady job where they save a considerable portion of their wages, and look forward to a home in the old country as an ideal, is all sufficient. They do not even know whether they are working in a gold or a copper mine. It is the job they want, without any reference to where it is so long as it pays. There is no interest or fascination to their work. As this type of labor now represents about two-thirds of the men around the mines, it is easy to see the reason for the decrease of the number who were willing to 'stake a pal' or 'take a chance' themselves ten years ago. Whisper in any of our Alaskan towns that gold has been found on some of the creeks hitherto unknown, and every English-speaking miner that can get away is off on the stampede and the 'bohunk' grabs the job that is left. The new camps are settled by English-speaking people; the foreign element comes when conditions are settled and work by the day may be obtained. Thus with the decrease of the easily found placers (or lodes), the American turns his attention to other lines and the foreigner settles down to the routine work.

Ore

The Editor:

Sir—No one appreciates the good fun in Mr. Gow's letter more than the not unhappy victim of it. The compliment that I most appreciate is criticism that manages to be both penetrating and polite—like that of the gentleman in Sumatra. As I have said elsewhere, I am not a professor but only a professional, merely an engineer become editor and therefore claiming no right to pass judgment on technical writing except in so far as any professional is entitled to give hints to amateurs. The fact that my living is made by the exercise of the pen, and the fact that I have a keen delight in learning to write well, does, I believe, justify me in elucidating principles and in criticizing errors in technical writing. That claim does not for a moment include the assumption that my own writing is above reproach—it would be absurd to say above criticism—for I am delightfully conscious that every year I learn more words and acquire a little more command in the use of them. Most of the errors against which I protest can be found illustrated in my own writings, but more in those that are least recent, for I try to practice what I preach. Not with complete success, as Mr. Gow has discovered. Undoubtedly, 'which' in the case quoted, is definitive and should be replaced by 'that'. This distinction between defining and non-defining clauses, with the consequent choice between the relative pronouns, is one that I have taken pains to advocate, and usually to apply. Therefore, the definition ought to read: "Ore is metal-bearing rock that, at a given time and place, can be mined at a profit," *not* as Mr. Gow phrases it, "that can, at a given" etc., be mined. It is an error to split your verb. Permit me to assure Mr. Gow that it is not done in the best families. As regards 'today,' I spell it without a hyphen for the same reason as a great many other progressive people do so, and therefore as most of the leading newspapers of America, because the hyphen in to-day has ceased to perform any grammatical function; it is atrophied. The 'to' and the 'day' are no longer betrothed, but married; they constitute a verbal unit. It is estimated that 200,000,000 persons write to-day, to-morrow, and to-night three times daily, on average, wasting thereby, in hyphens, enough energy collectively to propel an ordinary passenger train round the world.

In regard to the redundancies and contradictions against which Mr. Gow tilts so cheerfully, I demur to the contradiction, and I accept the redundancy. In the text of the lecture, from which my critic quotes, I was more anxious to be explicit than to be academic. Repetitions and redundancies are hardly blemishes in a lecture, when an effort is being made to emphasize a particular point. If I am only redundant on such occasions, I shall not be ashamed. However, I end, as I began, with raising my lance in salute to a discerning and amiable critic.

London, February 18.

T. A. RICKARD.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Electric blasting is causing considerable discussion on the Rand.

Temperature increase in 13 Rand mines from depths of 980 to 2000 ft. varies from 1° in 61 ft. to 1° in 134 feet.

Sand filling of stopes in the Angelo mine on the Rand costs 10 cents per ton of sand lowered. This is done by the 'flushing' system.

To obtain the highest practical effect from a given charge of explosive, it is generally considered important that there should be no air spaces between the explosive and the side of the hole.

Miners take many risks, in spite of repeated warnings. Tamping dynamite in holes to be blasted should only be done with a wooden rod. A man in the Ivanhoe mine, Kalgoorlie, recently tamped a hole with a steel drill 9½ ft. long, which resulted in the drill being blown through his shoulder.

Lumber for dredges should be properly seasoned before use in construction. Green timber shrinks as it dries, and would pull dredge gear out of line. It is also necessary, where timber is liable to be wet and dry alternately on a boat, such as that near the bucket line, to cover it with flat iron to prevent rotting.

Dangers in mining are many, and accidents are simple causes. A mine in Victoria, Australia, was recently unwatered, and on two men entering a raise above the 200-ft. level, an explosion occurred, although neither was hurt. Gas had evidently accumulated and been compressed by the water into the top of the raise, and the lights exploded it. Old winzes in mines gradually fill with water, which gets foul if there is no drainage. When driving raises to connect with such winzes, care is needed, especially when nearing the bottom of the winzes. A drill-hole should be made through the intervening ground, and the water gradually drained through it. In Western Australia, several years ago, two men lost their lives through a sudden rush of water from a winze to which they were driving in a raise.

Shafts now being sunk by the Oliver Iron Mining Co., on the Mesabi range, Minnesota, are being equipped with concrete sets. The concrete 'timbers' are made of the same size and framed practically the same as their wood prototypes, with the exception that the wall and end-plates are given a bevel in a

vertical plane at the end to help the corner bearing. The reinforcing is ¼-in. rods throughout, although it would seem that expanded metal or wire mesh would be better for the laths. The standard spacing of the sets is 5 ft., and the wall and end-plates are 12 by 12 in. The laths are 4 in. thick and 4 ft. 2 in. long. The tops and bottoms of the wall and end-plates are notched at the outside, so that the laths are set flush with the back of the sets. The wall plates are heavy, weighing about 3300 lb., and are rather hard to handle in the shaft, but are said to be giving good satisfaction when installed. The Company maintains a concrete plant at Hibbing for making the sets, and ships them to the various mines. The bearing timbers are large steel I-beams, which are cased with concrete after being placed in position. The part of the shaft from the first bearing set to the collar is usually made monolithic. The sets are carried as close as possible to the bottom in sinking, but the dividers for the last four sets are of wood, which is removed and the concrete dividers placed as the work of sinking progresses. The miners claim that, although heavy, the sets go into place nicely, and it is possible to install them just about as quickly as the wood sets. The hangers used are of 2-in. round iron, with a ring in one, and a hook in the other to facilitate removal in case of necessity.

Orebodies are often below the beds of lakes, rivers, or the ocean, and their extraction is dangerous until arrangements have been made to cope with the water. Instances of this are found at Cobalt, Ontario, where Kerr lake has been drained, and Cobalt lake is being emptied to get the rich silver ores; coal mining under the sea in Japan and Australia; tin mining under the sea in Cornwall, England; iron mining under the sea in Nova Scotia; and gold and silver mining under a river at Karangahake, New Zealand. The latest instance of ore recovery is in the Mesabi iron range, Minnesota, where it is reported that the Oliver Iron Mining Co., the mining subsidiary of the United States Steel Corporation, has made an appropriation to drain Carson lake, covering an orebody in the vicinity of Hibbing. This work is said to involve the pumping of about 200,000,000 gal. of water. The contract has been let to construct a ditch to carry the water to Kelley lake. The water is to be pumped by three large centrifugal pumps, presumably motor driven, placing the machinery on a barge and extending the discharge pipe as the water recedes. Shafts are to be sunk as soon as the lake is dry, and an attempt will be made to operate the property as an underground mine, as the over-burden is too heavy for the best results with an open-pit mining method. The amount of water to be handled in the underground system may necessitate a change later to an open pit, but this can only be definitely determined after experiments have been made. The fee of the property is owned by the state, which will derive a large sum in royalties from the work.

Special Correspondence

LONDON

DOLCOATH TIN MINE DEVELOPMENTS AND PAST HALF-YEAR'S RESULTS.—THE EXPLORATION COMPANY AND ITS INVESTMENTS.

About a year ago I recorded that the bottom levels, over 3000 ft. in the Dolcoath mine were poor, and that R. Arthur Thomas, the manager, had decided to prospect laterally in order to find the continuation of lodes that had in earlier days been worked for copper. These are known as the Entral lodes. It was of course unfortunate that just as the new vertical shaft costing £100,000 had reached the bottom levels concentrate per ton of ore has continued to decrease. The statement for the half-year ended December 31 has just been issued, and it shows that the condition of things is even worse than anticipated, and the quotation of the shares on the Stock Exchange has been knocked badly. The yield of concentrate per ton of ore has continued to decrease. The figure for the half-year was 29.3 lb. per ton, as compared with 30.2 lb. during the first half of the year, 32 lb. a year ago, and 79 lb. during the present Company's first half-year ended December 1895. The amount of ore milled was 56,409 tons, as compared with 58,304 tons during the previous half-year, and 60,631 tons a year ago, and the yield of concentrate was 738 tons as compared with 786 tons and 868 tons respectively. The Company has also been hit by the drop in the price of tin, and the receipts were only £79,672, as compared with £105,964 and £119,486, the average price of black tin having been £107 as compared with £134 and £137. Other items of revenue brought the total income to £80,736. The working cost was £65,293, and the lord's royalty £5311, leaving a profit of £10,131, out of which £4966 was written off for depreciation, leaving a divisible profit of £5165. Bringing £16,858 forward from the previous year, there was a disposable balance of £22,023. Out of this, £8750 has been distributed as dividend, being at the rate of 6d. (12c.) per share. The dividend for the first half of the year was double this, and the total dividend for 1913 was 7½%, as compared with 25% in 1912. During the half-year development at depth has been generally unsatisfactory. The drift on the Entral lode at the 1260-ft. level has not come up to expectations so far, but of course only a small part of the length of the lode has been explored. Results to be obtained at the intersection of the lode at the 1140 and 1380-ft. levels are anxiously awaited.

The doings of the Exploration company are always followed closely in America, for it has interests in Colorado, at El Oro, Mexico, and in the Natomas Consolidated company, besides having investments in Cananea and at Chuquicamata. It was formed in 1886 by two celebrated American mining engineers, Hamilton Smith and E. G. de Crano, with the financial backing of the Rothschilds, Barings, and other bankers and brokers in London. After the death of the original promoters, a period of misrule supervened, but shortly afterward R. T. Bayliss was appointed to the management and he restored its credit and some of its prestige. The Company has been hard hit by the disorders in Mexico, and by the depression in financial circles and on the Stock Exchange, so that the directors are not in a position to declare a dividend for 1913. Owing to the suspension of dividends by many of the companies in which shares are held, the gross income for the year was only £30,393, as compared with £80,644 the year before. After deducting administration expenses, a net profit of £10,058 was left. Owing to the fall in the market quotations of the shares held, the 'sundry investments' item in the balance-sheet has shrunk by £64,487; and now stands at £579,806. Owing to the serious position in Mexico, the subsidiary,

the Exploration Company of England and Mexico, formed to conduct search and development work in Mexico, was forced to suspend operations in January 1913, as the conditions in the country made it quite useless to spend any more money there. The El Oro company has fortunately so far been able to continue operations, and the physical condition of the mine shows improvement, but the directors have considered it best to suspend the payment of dividends. The Buena Tierra mine, in Chihuahua, has been in the centre of the conflict in the northern states, and though it was not itself in a vulnerable position, operations have only been intermittent, and the smelter to which the ore is shipped has not been running regularly. The latest advice is to the effect that the smelter resumed operations on February 1. The Santa Rosa mine in Zacatecas is in a more serious plight, for the destruction of the railway made it necessary to stop construction work in April of last year, and all development ceased in December. The property is now in the hands of watchmen, and so far is uninjured. It is particularly unfortunate that this cessation has been necessary, for the metallurgical difficulty that at first threatened has been overcome, and the mine is developing beyond all expectations.

The copper interests of the Exploration company have been increased by £87,000 by the purchase of convertible bonds in the Chile Copper Co., which operates the Chuquicamata mine in Chile. Chuquicamata is undoubtedly one of the world's greatest deposits of copper, for it is estimated that upward of 200,000,000 tons of ore averaging over 2% copper has already been proved. As readers of the journal are aware, the mine is controlled by the Guggenheims, and Fred Hellmann is manager. The money necessary for the equipment of the property with a plant of 10,000 tons daily capacity has recently been provided by the issue of convertible bonds, and it is expected that the plant will be in operation some time during 1915. This plant should produce 120,000,000 lb. of electrolytic copper per year, at a cost not exceeding 6c. per pound delivered at European ports. With copper at 14c. per pound the yearly profit would be £2,000,000. Mr. Bayliss has always had great faith in copper investments, and as opportunity offers no doubt the Exploration company will expand its investments in this direction.

NEW YORK

SHANNON DEVELOPMENT AND PROSPECTS.—BRADEN FINANCES.—HOMESTAKE.—YUKON GOLD, TONOPAH EXTENSION, AND GOLD-FIELD COMPANIES.

The Shannon Copper Co. has had a fortunate windfall. The Arizona Copper Co., which has a side-line agreement with the Shannon, was recently exploring in a part of its ground which adjoins the Alaska claim of the Shannon and developed a vein 30 ft. wide, averaging 8% copper, but in the Shannon ground. As the Shannon holdings extend for a thousand feet along the vein thus discovered, the find is likely to prove of a good deal of importance, though it is about a mile from the present main workings of the Shannon. The Company has just changed its fiscal year so as to correspond with the calendar year, and the report just given out therefore covers the period from August 1912 to January 1, 1914. In that period Shannon has produced 18,800,000 lb. copper at a net profit of \$480,000. The Company has \$200,000 in cash assets and is buying in the bonds of the Shannon-Arizona railroad, which connects the mine with the mill and smelter. The Shannon has passed through many difficulties, but has been excellently managed and apparently has a brighter future.

New financing for the Braden is like the relief of Ladysmith in the Boer war. On even dates it is affirmed and on the odd denied. Now that the ore reserve has been so greatly increased, the next thing will be to increase the capacity of the mill and smelter. This requires money. Probably what will

be done will be to issue the \$1,000,000 remaining of the second mortgage convertible bonds which have been authorized, selling them to the Guggenheim Exploration Co., which already has over \$11,000,000 in cash and demand loans, and has recently increased its dividend rate to 14% per year. Pope Yeatman is expected to reach New York next month and the latest information regarding the position of the mine will then be available.

The Homestake has just made its report for last year, which makes possible some interesting comparisons with the preceding year. During 1913 the income of the Company showed a decrease of about \$500,000, but the dividends were increased from \$1,310,400 up to \$2,146,225, thereby converting the surplus of nearly a million dollars, which was on hand last year, into a deficit of \$27,710. The capital stock has been increased nearly \$4,000,000 during the year and it is reassuring therefore to find that T. J. Grier, the superintendent, reports the property in fine physical condition, with over 2,000,000 tons

SOME OF THE HOMESTAKE MILLS.

of ore broken in the stopes, and the prospects for a long and profitable life of the mine bright in the extreme.

Yukon Gold shares have been picking up, probably as a result of the good showing made in the report for 1913. With a gross output of \$4,789,402 it showed operating profits of \$2,537,447. The eight Dawson dredges made profits of \$1,827,800, while the hydraulic work at Dawson showed a loss, since most of the season was spent on washing top gravel. The dredge working in the Iditarod made a profit of \$507,800 and should do better next year. The two dredges in California brought in profits of \$72,000 but one of them has only been at work a short while. Some comparisons of cost will be of interest. The hydraulic work at Dawson cost 9.7c., dredging at Dawson 29.53c., and at Iditarod 64.33c. per cu. yd. This high cost is largely due to the collateral and overhead costs, thus at Iditarod a series of dams had to be built before and behind the dredge, large boulders gave trouble, as did heavy sand from workings above, and a stratum of clay which was encountered. The grade was steep, 6 to 10%, and the scarcity of water all combined to make the necessary dredging cost nearly fifteen times what it is in the more favorable California areas. It is necessary for the Company to write off large amounts as depreciation each year and it still owes the Guggenheim Exploration Co. \$2,100,000.

Topopah Extension has proved a disappointment to those who expected big things of it a year ago when it was making a net operating profit of over \$25,000 per month. The earnings have shrunk until they are barely one-half of what they were and last December operations showed a loss of \$8,000 for the month. Goldfield Consolidated, on the other hand, refuses to die, and its recent declaration of a dividend of 30c. per share, payable April 30, was more or less of a surprise to everybody. The controversy between the West End and the Jim Butler is still a topic of interest, but nobody seems to have any clear idea of what the outcome is likely to be.

JOPLIN, MISSOURI

ANOTHER OLD PRODUCING TRACT IS DRAINED.—QUAPAW, OKLAHOMA, DISTRICT RESUMES PRODUCTIVENESS.—ACTIVITIES THROUGHOUT THE MISSOURI-KANSAS-OKLAHOMA DISTRICT.

The drainage of old tracts that once were well known producers forms some of the more important mining development throughout the district at the present time. In addition to the drainage of the Lone Elm region, as noted in this journal on February 14, similar activities have been launched on the Cox land in the Turkey Creek bottoms, in the extreme northern part of the city of Joplin. A tract of land, once dotted with mills and smaller mining plants, later to be abandoned for many years, has now been drained to a depth of 80 ft. by the Oak Orchard Mining Co., and work is well under way on the construction of a new concentrating plant of 150 tons daily capacity. It will be used as a custom mill, over which the heavy tonnage of ore from numerous small prospects will be cleaned. Associated with this Company are A. R. Snyder, county coroner; George Quinby, former state mine inspector; Rev. W. M. Cleaveland, pastor of the First Presbyterian church of Joplin; and A. J. Johnson, H. J. Vancil, Nathan Rosenberg, and E. W. Hoffman, all business men of Joplin. At a depth of 70 ft., Miller & Warren are working a 20-ft. face of zinc ore which is showing a mill recovery of nearly 10%. Walker & Co. have a 27-ft. face of soft ore at the same depth; Lee & Westerman, also at 70 ft., have a 14-ft. face of 15% ore; Scott & Co. are operating at 50 ft. and have ore. Until the new custom mill is completed, the operators will continue to haul their ore to another custom plant, more than a mile distant.

An isolated mining camp, Quapaw, Oklahoma, of which little has been heard during the past year, is again taking a place in the list of producing camps of the district, two mines, the Ethel Miller and the Newlands, being the only productive properties just now. Operations at these, each of which is equipped with a small concentrating plant, were started recently. The output of this area will probably be increased when work starts at the Mission mine, now under the management of Wheeler & Hardy, who also have extensive mining interests at Joplin. The Mission mill, remodeled more than a year ago and then left idle, has a capacity of 400 tons per shift, and is the largest plant in the Quapaw field. It was the first mine of importance in the northeastern Oklahoma district, and has been operated by possibly a dozen different companies. At this mine work is conducted at a depth of 140 ft., the deepest at Quapaw, all other development being above 100 ft. In drilling operations, little deep work has ever been undertaken, but the plan of the company, that now has the Mission, is to put down a number of holes to a depth of over 300 feet.

Several new concentrating plants are under course of construction at various points throughout the district, but the greater part of mining activity consists of the removal of old mills to new mines, where they are reconstructed and remodeled. Considerable new equipment is necessarily required, and local machine firms report business to be somewhat better than for some time. In the West Joplin camp, the Geronimo mill, formerly operated by J. M. Short, has been purchased by the Underwriters Land Co., one of the large companies of the district, and work has been resumed at the property. Another new mill in the West Joplin field is that of the Otis Mining Co., the capacity being 350 tons per day. A new shaft is being driven, work being conducted from above and below, the underground activities being carried upward from an old drift of an adjoining mine, the Hero, which had cut over on to the Otis lease in former years. At Spring City, the Quaker Maid mill will soon be ready for operation. On the St. Louis-Joplin Lead & Zinc Co.'s land at Chitwood, the Kentucky Lead & Zinc Co. is

constructing a new mill of 150-ton capacity. Ore has been blocked out at a depth of 142 to 164 ft. Within a short time a contract is to be let for the construction of a new plant on the A B C Mining Co.'s lease of the St. Louis-Joplin land, where, about a year ago, the former mill of the A B C company was destroyed by fire. This mine was one of the most prolific producers of high-grade zinc ore in the district at that time.

S. A. Nichols and associates, of Joplin, have leased the Everett Zinc & Lead Co.'s property at St. Joe, Arkansas, from the Graves Mining Co. of Doe Run, Missouri, and they plan to construct a 100-ton concentrating plant. The Arkansas property is situated in Searcy county, from which some zinc and lead ore shipments have been reported.

DEADWOOD, SOUTH DAKOTA

THE HOMESTAKE COMPANY'S VETERANS' ASSOCIATION AND RECREATION HALL.—NEW MOGUL MILL.—WORK AT THE DAKOTA CONTINENTAL.—OIL WELL AT ARDMORE.—THE BEAR LODGE DISTRICT.

Now that there is so much discussion about 'subsidiaries,' 'interlocking directorates,' 'combinations,' etc., it might be interesting to note that the Homestake Mining Co. might some day be assailed for fathering subsidiaries. But so long as these are not combinations 'in restraint of trade,' they will continue to operate. One of the subsidiaries of this Company is known as the Homestake Veterans' Association, and to prove that it is a doubtful concern, it would be well to glance at the list of officers. They are all 'interlockers' of the best variety, and include the superintendent and assistant superintendent as well as several heads of departments. But the association need have no fear of the Interstate Commerce Commission, Congress, the Bureau of Corporations, or other governmental authority, for its mission is to promote loyalty, good will, and a closer fellowship among the employees. To be eligible to membership, a man must have been in the employ of the Company for 21 years. The roll of the association shows that there are now 120 members in good standing, and the waiting list includes about 2000 more, who are anxious to join, but are barred by short lengths of service. That the association is popular is testified by the rapid growth in membership. Men join the moment they are eligible. The officers are: president, Richard Blackstone, assistant superintendent; vice-president, W. J. McMackin; secretary, Robert Fraser; treasurer, John A. Spargo; trustees, T. J. Grier, superintendent, and William Ryan. Some idea of the immense amount of labor that has been expended on Recreation hall, the clubhouse the Homestake Mining Co. is erecting for its employees, is noticeable to the visitor to the building, now that what may properly be termed the finishing touches are being added. Interior plaster and calclining is white, and is practically completed throughout. Now that a large part of the rafters and supports in the theatre have been removed, the theatre is assuming a finished appearance. The balcony of the theatre will be one of the features, for each and every seat will be as good if not better than most of the main floor seats. The ceilings are high, and permit of good and airy spaces above the balcony, and the acoustics promise to be of the best. In the basement all the plastering has been finished, and in the bathing room the cement floors have all been laid and the enamel rim of the pool is completed. The pool is 75 ft. long, 25 ft. wide, and has a maximum depth of 10 ft. and a minimum of 4 ft. Shower baths will be in the corners of the swimming room and dressing rooms and lockers in adjoining rooms.

The new mill of the Mogul Mining Co., at Terry, was started at part capacity on February 1, and since has been

given a thorough test in all departments. It is encouraging to note that the De la Vergne oil-engine, the first to be installed at any Black Hills mine, is working well, and, it is claimed, with great economy as well. E. R. Graham is superintendent, L. D. Dougan in charge of the mill, Charles A. Chase general manager, and J. V. N. Dorr consulting engineer.

Sinking has been resumed by the Dakota Continental Copper Co. at Hill City, after considerable difficulty and expense in removing water. The shaft was 823 ft. deep and was unwatered to the 700-ft. station with one 4 and one 6-in. air-lift. At this station a Rumsey triplex, electrically driven, 400 gal. per minute pump was installed, and with its aid the shaft drained. It is proposed to sink the shaft to the 1000-ft. level, cut a station and sump, remove the pump to this station, and start prospecting. From diamond-drilling previously done, it is figured that 300 ft. of lateral work will cut a body of 're-deposited' copper ore. Ingersoll-Rand jack-hammer drills are being used in the shaft. W. J. Booth, of Hill City, is in charge of operations.

A trial shipment of 20 tons of \$16 gold ore from the Heidelberg property has been sent to the Golden Reward mill at Deadwood. This is the property which was selected for development by a committee appointed by the Deadwood Business Club after a number of promising prospects were examined, and the results so far would indicate that a wise selection had been made. Citizens of Deadwood are making regular monthly subscriptions to the development fund, and work is being pushed with a small crew. In addition to the shipping grade ore, a large quantity is being piled on the dump that would pay well to mill in a plant on the property, and just as soon as development warrants such a step, it is probable that the property will be offered for sale, and the profits used to develop other properties.

The well of the Ardmore Oil Co., at Ardmore, has recently been cased with 10-in. casing to the 1200-ft. point, and now that the size of the hole has been reduced, better progress is anticipated. It is expected that the Dakota sandstone, the oil-bearing rock of the district, will be reached at about 1600 ft. The well is a little over 1300 ft. deep.

A. E. Hall, superintendent of the Anaconda Gold Mining Co., is authority for the statement that important work will be started on this property. Funds are now being raised for development, and it is planned to do some extensive work on the north end of the mine, where some excellent surface showings have been discovered. It is probable that a new shaft will be sunk there. Otherwise lateral work from the old shaft will be attempted. The property is one of the best in the Roubalx district, and has been partly developed, but never equipped with a mill.

The Warren Peak Mines Co. has just received patent to its property in the Bear Lodge district. This is the first property in this district to be deeded by the Government. The tract includes 392 acres. The most important ore so far discovered in shallow workings is a streak an inch or so wide, carrying sylvanite, and often yielding assays up to hundreds of dollars per ton. It has been stated in the past that the Company hesitated to prosecute extensive development until more was secured. Considerable activity is apparent in the Bear Lodge district, nearly a dozen properties now undergoing active development, and the next few months promise to witness important exploitations. It is a little early to prophesy, but from surface indications it seems that this should develop into a good mining camp.

The annual report of the Wasp No. 2 Mining Co., operating at Flatiron, shows that 127,680 tons of ore was treated, yielding \$219,335. Operating costs were \$167,392, and net profit \$24,543. Dividends amounted to \$55,000 equal to 11% on the capital. Operating time was 8.3 months. Detailed costs will be given in another issue of this journal.

JOHANNESBURG, TRANSVAAL

ANOTHER STRIKE, ITS CAUSES AND RESULTS.—VALUE OF ORE AT DEPTH AND WAGES.—CINDERELLA CONSOLIDATED SHUT DOWN.—AIR-BLASTS AND CAUSES.—GOLD PRODUCTION.

Another strike broke out in the Transvaal at the beginning of the year, and threatened to have more disastrous results in the mining industry than the previous strike in July, when all the miners came out on strike for several days. The railway men of the state went out on strike against the dismissal of several employees, and paralyzed the railway service in the Transvaal and part of Natal and the Orange River State. In Cape Colony, the railways continued to work as usual. Unless the strike was settled within a week the whole of the gold mines would probably have been shut down for want of coal. About six of the strike leaders were arrested, and along the 'reef', from Randfontein to Springs, a distance of about 50 miles, the mines and railway were guarded by over 10,000 troops. The Transvaal government did not, as was unfortunately the case in the last strike, attempt to interfere with the men holding public meetings. The strike leaders still out of prison threatened to declare a general strike unless the imprisoned leaders were liberated. At the last mass-meeting held, it was decided to submit the question of a general strike to a ballot of the men, but so long as the railways were paralyzed by the strike, a general strike would not add much to the inconvenience, as before the result of the ballot could be acted upon many of the gold mines would be crippled for want of coal. As mentioned before, the outlook for the gold mines was bad, and should work from any cause have been suspended it would have had a disastrous effect upon the native labor supply, which since the last strike has been in a precarious condition. There has been considerable discontent among the skilled men employed in the railway workshops for some time, which made to some extent an uneasy feeling in other branches of the railway service. It was, however, in the workshops that most dissatisfaction prevailed, and sooner or later it was evident that a strike must follow. The railway men depended on the gold miners for support in their dispute, but the latter only gave a half-hearted support. Some mines were thrown idle, but the miners' organization was so defective, and a general strike unpopular, that they continued to work. In South Africa the conditions are such that a general strike is extremely difficult to bring about. Most of the work is done by unskilled and uncivilized natives, who have no idea of combining to promote their own interests, and with a few Europeans to act as supervisors work can proceed almost the same as usual on the mines. The natives are not allowed to form societies, if they could, to protect their common interests, and all they desire is to earn sufficient money to enable them, in comparative plenty, to return to their *kraals*. At the present time, January 22, the strikers are asking to be allowed to return to their duties unconditionally, and to all outside appearances the strike is virtually over. It remains, however, to be seen whether force employed to the extent it has been used on the Rand against the workers will completely crush out the strike movement. Among those arrested during the week for attempting to persuade railway workers not to return to work, was F. Cresswell, member of the legislature, and nearly every union leader of note has been placed under lock and key. Outwardly the strike appears to be over, but while a lesson, and that a severe one, has been taught to the men, there are not wanting those who consider that, owing to the overwhelming force displayed to end the strike, it is not improbable that the workmen will reorganize and watch their opportunity to again cause trouble.

{The arrest, deportation from South Africa, and the recent

arrival in England of the strike leaders, with the public opinion on this action, has been published in the daily papers from time to time.—EDITOR.]

The abortive attempts at a general strike, and the determined manner in which they were met by the Government, have caused the question to be raised as to whether the miners will be able to maintain the present high rate of wages for long. The fact that the 'reef' on the Rand, in the majority of instances, has become poorer at increased depth cannot be denied, and there are several instances where the value of the yield and the cost of working are too close to yield any dividends for shareholders. The indications for the future point in the direction of these mines increasing in number as greater depths are attained, as no matter what may be said to the contrary, working costs are bound to increase with depth, and if such increased costs are accompanied by a lower yield, the tendency for profits to attenuate is materially hastened. The need, therefore, for lower working costs must increase as time goes on, and as a last resource wages will have to come down in the inevitable pending struggle to work the deeper mines at a lower cost. The cost of living on the Rand has been materially reduced of late, far more than wages; but while the phthisis scourge may always tend to keep up wages, as mining becomes less profitable with depth it is evident that costs must come down and that wages will have to some extent contribute toward the relief.

The circumstances surrounding the closing down of the Jupiter mine, the deepest gold mine on the Rand, referred to in this journal of December 6, 1913, have not been ameliorated by a similar step being adopted at the Cinderella Consolidated mine, near Boksburg, on the East Rand. Like the Jupiter, the Cinderella Consolidated was working at a depth of from 4000 to 5000 ft., but unfortunately it was a single-shaft property, for although an outlet was obtained with the East Rand Proprietary mines, it did not in any way better the underground conditions, although it removed the restrictions imposed by the mining regulations on mines working with a single shaft in the Transvaal. The Cinderella Consolidated has had a somewhat checkered career, as while the ore sent to the mill was well up to the average of that milled on the Rand, the working costs were so high that for some time past milling operations resulted in a loss. Change of managers did not improve matters. The monthly losses continued, so it was decided to close down the mill and not waste the ore reserves of the mine by attempting to run the mine before the second shaft, in course of sinking, had been completed, and connected with the underground workings. After ceasing milling operations it was found that it was impossible to obtain the additional working capital necessary to place the mine in good condition, including the completion of the necessary underground connection, and it was reluctantly decided, as in the case of the Jupiter, to close down the Cinderella Consolidated entirely and await the arrival of better times. Underground difficulties have always been a prominent feature of this mine, apart from that of procuring ample ventilation, through the mine having for a long time only a single shaft. In the shallower part of the mine, about 4500 ft. from the surface, air-blasts frequently made their presence felt, good stopes being frequently lost for some time owing to this cause, and the working costs and difficulties considerably increased. These air-blasts appear to have had their origin principally through dikes and broken ground preventing underground subsidence taking place in a uniform manner. The leaving of pillars to steady the subsidence only added materially to the difficulty, and so strong were the air-blasts that several lives were lost through their occurrence. Probably had the whole of the 'reef' been extracted, and systematic sand filling been resorted to, these difficulties would have been reduced to a

minimum. It requires a bold mining policy to handle Rand mining properties at a depth of 4000 ft. from the surface, and in no instance has sufficient pluck been yet displayed to adopt such a wholesale mining policy as is fast becoming necessary on the deep mines of the Rand. So far, closing down the mine has been considered preferable.

The Transvaal Chamber of Mines has declared the December output of gold for the whole of the Transvaal as 672,815 fine ounces, valued at £2,857,938, being a decrease of 671 oz. compared with the preceding and shorter month of November. This declaration was disappointing, because it was at least expected to reach in value £3,000,000 and restore the gold output of the Transvaal to something approaching its normal condition. This unsatisfactory output for December shows how chronic and disastrous the scarcity of native labor has become and how difficult it will be in the present epidemic of strikes to maintain the progressive nature of the Transvaal gold output, one of its chief characteristics for the last 27 years. The total gold output for 1913 was 8,794,824 oz., valued at £37,358,040, being a decline for the year of 329,475 oz., valued at £1,399,520, when compared with the output for 1912.

Prospects for the current year are even worse. There is also the fact to be considered that the Jupiter, Cinderella Consolidated, and Treasury mines have been closed down during the year, and there does not seem any prospect of new producers taking their places. It must not be forgotten that every year sees one or more of the richer gold mines on the outcrop of the Central Rand exhausted and merged into its less profitable deeper neighbor, so that the conclusion is that the gold output of the Rand will soon reach, if it has not already reached, its maximum proportions.

DULUTH, MINNESOTA

WEATHER CONDITIONS.—INCREASING THE GRADE OF ORES.—EXPERIMENT STATION OF THE SCHOOL OF MINES.—PICKANDS-MATHER OPERATIONS.

The present cold weather has been continuous, and with the aid of a good fall of snow has made it possible for the logging contractors to get their usual quota of mining timber to the railroads, and shipments to the mines promise to be made on schedule time in spite of the late start. The cold spell has caused a great many stripping operations to cease, and the men are now employed in making repairs to the rolling stock and shovel equipment.

The subject of ore beneficiation is receiving constantly increased attention just now, and many companies are conducting experiments to determine the possibility of making a shipping grade out of their low-grade ores. These ores are a source of trouble to many mines now operating, as they are so situated as to handicap operations seriously. In the steam-shovel mines, in many cases, it is necessary to load large tonnages and haul them to lean ore dumps to get at the shipping ore, and the underground mines have to make lean ore dumps necessitating a classification of the ores sometimes into three or more products. This complicates the stockpile arrangements during the stocking season, and during the shipping season necessitates the operation of the haulage system on the stockpile in addition to loading directly from the shaft pocket into the ore cars. So, any process which can be devised to make a shipping grade of these ores will be a great benefit to mining operations, although it might not be expedient to treat the ores alone. Several mines have been obliged to suspend operations because the proportion of lean is too great to permit of profitable working. In some cases the leases are so loosely worded that there is dispute between the fee owners and operators as to the minimum grade to be handled, so the operators have closed down until an understanding can be reached and in several in-

stances the leases have been thrown up. The question of concentration involves many factors, and each case must be treated by individual investigation. The character of the ore, the percentage and locality of the phosphorus, silica, and other contents of the ore are matters which will determine the advisability of treatment, as well as the proportion of lean ore to shipping ore. Some ores will be made into high-grade bessemer ore by concentration, others will be made into high-grade non-bessemer from an apparently bessemer lean ore, while still others are not affected in grade to any appreciable extent by any process yet tried.

In this connection the Experiment Station of the Minnesota School of Mines is doing a valuable work for the state, and has just issued a bulletin, 'Preliminary Concentration Tests on Mesabi Ores,' by William R. Appleby and Edmund Newton. The bulletin describes the apparatus used in making the tests, gives working drawings, and gives the results in tabular and graphical form of a number of tests recently made for various companies and individuals. Some formulae are also given showing the relation of various results. The purpose of the station is outlined in the bulletin. It was established in the fall of 1911. Its purpose is to promote the development of the mining and mineral resources of the state to assay specimens of ores, clays, and minerals; to make such assays free of charge for private parties, subject to such regulations as the board of regents might deem necessary to make mining and metallurgical experiments in the treatment of such substances and in the utilization of mining and metallurgical by-products; to investigate the methods of mining and the use of explosives; to undertake such other mining and metallurgical problems as might seem desirable; to make all ore estimates for the tax commission and do such other work along the lines above mentioned as might be requested by other state departments. This is the second bulletin issued by the station, the first written by C. E. van Barneveld on 'Mining Methods of the Minnesota Iron Ranges' was issued last year.

The marketing of Mesabi ores involves complex calculations, and nearly all operators maintain a grading department working in conjunction with the laboratory. By combining ores of different grade from the same and different mines it is possible to ship much of the low-grade ore, and realize the higher price on it, or make a sale on ore that would otherwise be unsalable.

The Pickands-Mather company is carrying on an interesting piece of work at the Bangor mine, near Biwabik. It had a set of five boilers, of which it was necessary to keep four in constant operation to handle the water flow of 4000 gal. per minute. The boilers are being re-bricked and Toledo Model stokers installed. An extra boiler was put in at the end, making a battery of six, as it was necessary to have two boilers cold while the work of bricking-in was going on. This work has been carried on successfully without any hindrance to operations. When the brick work has been finished, and the stokers are placed, an economizer will also be installed. The stokers use slack coal, a much cheaper fuel, and it is said that the rate of steaming has also been increased by their use. This is the first installation of mechanical stokers on the range and it is likely that others will follow.

The Pickands-Mather Co. has given up its lease on the Virginia mine between Eveleth and Virginia, and has moved its shovel equipment to headquarters at the Elba mine, near Gilbert. The royalty paid on the ore was the highest ever paid on the Mesabi range, \$1.35 per ton. The reason assumed for giving up the lease is the large percentage of low-grade material necessary to be handled in removing the ore, and differences with the fee owners in interpreting the lease. The Company has stripped the property, and already removed over 300,000 tons of unsalable low-grade ore in the course of operations.

General Mining News

ALASKA

CHISANA

A well illustrated description of the Chisana goldfield has recently been published in *Bulletin* 24 of the Canadian Mining Institute, Montreal, by D. D. Cairnes, of the Geological Survey of Canada. He made a trip to the new district in August of last year. The article covers the location, routes in detail, traveling expenses, previous investigations of the district, the proper name as above, topography, general geology, discovery, gold recovered, the gravels and their extent, value of the gold (\$16.10 per ounce), and the future.

ARIZONA

COCHISE COUNTY

The Shattuck-Arizona Copper Co. operates in the Warren district, and the report covers the period from August 1, 1912, to December 31, 1913. During this term the revenue from copper, gold, silver, and lead ores, etc., was \$2,562,668. Development, mining, marketing, and smelting of ores, etc., cost \$1,411,788. The net profit was \$1,150,879, out of which dividends were paid amounting to \$525,000. The net surplus at the end of 1913 was \$598,150. During the past calendar year results were as follows:

| | |
|------------------------------------|------------|
| Copper ore shipped, dry tons | 89,317 |
| Copper recovered, pounds | 13,219,756 |
| Lead ore shipped, dry tons | 4,874 |
| Lead recovered, pounds | 1,483,956 |

The ores are delivered to the Calumet & Arizona smelter, and the metals produced, are sold by Adolph Lewisohn & Sons of New York.

The general manager, Mr. Shattuck, reported that ore production has been regulated by the ability of the Calumet & Arizona new smelter to handle the Company's ores. New orebodies are being opened in the mine, which is looking excellent. Prospecting around the Shattuck fault has given

HYDRAULICKING AT THE OLD ECHO MINE, MURPHYS, CALIFORNIA.

promising results. Two small shoots of good ore were opened on the 200-ft. level. A variety of ore, including \$30 gold ore, silver-lead ore, and copper-lead ore, has been opened on the 300-ft. level. The copper-lead ore requires careful sorting. Extensive shoots of copper ore have been opened at 400 ft. The new orebody at 500 ft. is mostly an iron ore containing 6% copper. No. 6 level produced about 50% of the ore shipped from the mine, and reserves have been maintained. A large shoot of lead carbonate ore was opened on this level, and it should yield 100,000 tons assaying \$2 gold, 2 oz. silver, and 18% lead. No. 7 level is promising, as also are No. 8 and 9 levels. Arthur Houle is superintendent of the mine. Unless arrangements are made to treat the rich lead ores produced, a lead smelter may be erected at the property.

During January, the Iron Cap mine, at Copper Hill, near Globe, produced 705 tons of ore yielding 117,309 lb. of copper, with a profit of \$7951.

GILA COUNTY

PINAL COUNTY

There is considerable activity in the new goldfield at Gold Creek, near Ray, and prospecting covers a length of 2½ miles. Claims are being sold, there are arguments about overlapping claims, surveyors are marking correct lines, and blasting is heard on all sides. The country is diorite and schist. It is said that the Ray Consolidated may take an interest in the district.

CALIFORNIA

During February the San Francisco mint received 157,890 fine ounces of gold and 24,105 oz. of silver, worth \$3,277,382.69, for coinage, from all parts of California and other states. The domestic coinage was \$153,000 and \$134,000 for the Philippine Islands. The coin and bullion on hand at the end of the month was worth \$236,010,362.22, and \$136,926.50.

AMADOR COUNTY

The flow of water in the Kennedy mine is about 16,000 gal. per day on the No. 36 level, this being the first water of any consequence below the 1800-ft. level. James F. Parks, superintendent of the Plymouth mine, has filed with the county recorder 14 blue-prints of the new mill, which is to be finished in 120 days from February 15, at a cost of \$27,568.

BUTTE COUNTY

The Hunter dredge, operated at Oroville by the Oro Water, Light & Power Co., is digging out a channel and making a levee or retaining wall to protect the Oroville-Marysville road, about five miles below the former town. The wall is 30 ft. high in places. This work has been under way for three weeks and will be finished in a week or so. C. G. Leeson is dredge manager for the corporation.

ELDORADO COUNTY

A 5-stamp mill has been erected by Philip Gamelo at his mine at Nashville. A large tonnage of low-grade ore has been developed at the Shaw mine, owned by San Francisco

people, headed by H. DeC. Richards. Three 10-ft. Lane mills will be installed to crush 150 tons per day.

NEVADA COUNTY

It had been reported that hydraulic mining at You Bet was being carried on in violation of the debris law, but Mr. Cheney, in charge of these matters in California, states that this is not so. It was also said that restraining dams built under government supervision on the Jerry Goodwin claims had been washed out, and the debris carried into the Bear river, and hydraulicking continued just the same.

PLACER COUNTY

A representative of the Guggenheim mining interests has made an application to the supervisors of this county for a

permit to construct a narrow-gage railroad from the Dairy Farm copper mine to Lincoln. This mine was developed at the time the San Bruno smelter was planned, and after lying idle for some years was reopened last year under lease to Newman and Beals.

PUEBLO COUNTY

Rich ore is said to have been cut in the San Jose mine, a mile below Seneca. This mine is owned by Hugh Kelly. Good ore has been opened in the claims owned by Wilson and Benner on Winters creek. It is opened by an adit 150 ft. long.

SHASTA COUNTY

The new 10-stamp Straube mill at the West End mine, at Whiskeytown, is working. Previous to this all ore went to the Gambrinus mill.

SISKIYOU COUNTY

(Special Correspondence.)—The Mt. Vernon mine has been taken under lease for three years by L. C. Dobbins and associates of Montana. The mine has been worked extensively in past years and is well equipped. Sinking is progressing at the Osgood mine, owned by F. H. Osgood of Seattle. The vein is widening and ore from \$20 to \$30 is being mined. A 5-stamp mill was recently placed in commission. W. Beall is superintendent. The mill at the Mono mine, near Humboldt, will be started early in March. J. Joley and O. H. Poor have taken out about 100 tons of good ore. Considerable work is under way at the Big Cliff, under the management of H. B. Wintering. It is reported that a small mill will be erected during the coming summer. Work was recently resumed at the King Solomon, which is controlled by Eastern people. W. H. Young is superintendent. The Klamath River Mining Co. is operating its placer holdings above Weitchpec with 10 men. C. H. Barton is superintendent. Another attempt is being made to recover gold and platinum from the debris carried into the Klamath river by the hydraulic and placer mines. A company of Idaho people has erected a small plant near Martin's ferry, consisting of a pump, screens, canvas concentrator, and a secret contrivance.

Yreka, February 28.

TRINITY COUNTY

(Special Correspondence.)—At the Golden Chest mine, in the East Fork district, 11 ft. of formation has been opened in the lower cross-cut, about 40 in. of which looks well. A drift will now be driven north on the vein to cut the main ore-shoot below the upper workings. This property has been practically closed down for several years, but has a good milling record. The further development of the orebodies should place it on the list of producers. The ore contains free gold, accompanied at times with high-grade galena which, with various tellurides, is characteristic of the district. T. J. Rochford, one of the owners, is in charge. Mr. Stofor, of Dedrick, has recently been in case on the property with the privilege of purchasing. He will begin active development on April 1.

Helena, February 28.

COLORADO

CHRYSLER COUNTY

(Special Correspondence.)—A streak of very rich sylvanite 4 in. wide has been cut on No. 12 level of the Gem mine, situated on Seaton mountain. The shoot is showing in a raise for 35 feet. E. Mosher is operating under lease. Coe & Co., operating on No. 12 level east, have opened a shoot of smelting ore 5 ft. wide, and shipments made return \$30 per ton. A carload of bornite ore sent out last week from the Sun and Moon mine brought a settlement of \$5000. This property is being operated by J. P. Olsen, and a force of 20 men is at present being employed. Work will be resumed in a few days at the French Flag mine in Gilson gulch. Operations had to be suspended following the storm of last December, it being

impossible to take in fuel. Chas. H. Ripley will return from Boston in a few days to take charge of development.

Idaho Springs, February 18.

OURAY COUNTY

Shipments of ore and concentrate from Ouray in February totaled 1040 tons from seven properties. The Wanakah Mining Co. has secured a lease of the Brown Mountain smelter. According to the Company's manager, John T. Roberts, Jr., there is 60 days' ore on hand; but silicious ores will be accepted up to a certain tonnage. During the last quarter of 1913, the Camp Bird company had the following results:

| | |
|----------------------------------|-----------|
| Development, feet | 1,265 |
| Stoping, cubic feet | 77,820 |
| Broken ore in stopes, tons | 14,663 |
| Ore treated, tons | 8,683 |
| Bullion receipts | \$111,917 |
| Concentrate receipts | 82,901 |
| Expenditure | 194,453 |
| Net profit | 89,465 |

Development on No. 6 and 7 levels proved little of special mention.

SAN MIGUEL COUNTY

During January the Tomboy mine produced \$33,000 in bullion, \$44,000 from 1000 tons of concentrate from 11,000 tons of ore, and a profit of \$3300 from the tramway. The profit was \$30,000. Owing to snowslides, described in this journal of February 7, power and tramway operations were interrupted for two days.

TELLER COUNTY (CRIPPLE CREEK)

Details of the estimated output for February are as follows:

| Plant. | Tons. | Av. value. | Gross val. |
|--------------------------------|--------|------------|------------|
| Colorado Springs: | | | |
| Golden Cycle | 25,300 | \$20.00 | \$506,000 |
| Portland | 9,500 | 18.00 | 171,000 |
| Denver and Pueblo smelters.... | 3,920 | 55.00 | 215,600 |
| Cripple Creek: | | | |
| Portland | 14,000 | 2.80 | 39,200 |
| Stratton's | 10,923 | 2.63 | 28,727 |
| Colburn Ajax | 4,000 | 5.00 | 20,000 |
| Wild Horse | 1,000 | 3.00 | 3,000 |
| Kavanaugh-Jo Dandy | 1,700 | 1.40 | 2,380 |
| Isabella | 650 | 3.00 | 1,950 |
| Rex | 300 | 2.40 | 720 |
| Total | 71,293 | | \$988,527 |

Owing to the short month and bad roads the output was lower than usual. The E. P. mine produced 2550 tons, lessees contributing 500 tons. At 17.00 in the No. 2 shaft of the Portland, water has caused a temporary stoppage of sinking operations. A station is to be cut at this depth.

The United Gold Mines Co. controls several subsidiary mining companies and lease 27 claims at Cripple Creek. The report covers the year ended December 31, 1913. No ore was produced on company account and the output by lessees amounting to 20,270 tons worth \$14.36 per ton, was made as follows:

| Mines and locality. | Tonnage. | Av. value. |
|---------------------------------------|----------|------------|
| W. P. H., Ironclad hill | 5,622 | \$24.47 |
| Damon, Ironclad hill | 314 | 10.02 |
| Montrose company, Ironclad hill | 329 | 12.00 |
| May B., Squaw mountain | 214 | 18.88 |
| Deadwood, Bull hill | 1,097 | 9.75 |
| Wild Horse, Bull hill | 1,500 | 24.63 |
| Requa company, Bull hill | 100 | 8.40 |
| B. H. & S. M. Co., Bull hill | 7 | 5.35 |

The Wild Horse mill was operated under lease and treated 11,593 tons, yielding \$89,206. Charges on the ore mined were \$85,652 and \$111,111 was paid to lessees, and the royalties were \$31,539. Net profit for the Company was \$14,823.

IDAHO

LEMHI COUNTY

On March 2 the second carload of ore from the Allie mine, at Gilmore, arrived at the United States Smelting company's plant at Salt Lake City. Assays indicate that the 50 tons may be worth \$17,500. E. C. Ross, president of the Allie Mining Co., figures on a carload each month, and an exceptionally rich shipment is being prepared. The vein is 4½ ft. wide, with high gold content, while 18 in. of it is worth \$1375 per ton. On April 1, the Gilmore Mining Co., adjoining the Allie, will sink its shaft a further 200 ft., making 700 ft. on the vein. The Gilmore produced about 1000 tons of \$18 ore in February.

SHOSHONE COUNTY

Ore and concentrate shipped from 14 properties in the Coeur d'Alene in February totaled 36,714 tons. Moving pictures are to be taken of complete mining operations in the Bunker Hill & Sullivan mine. Nash Wayland, one of the electricians of the Company, is in charge of the lighting for this purpose, having installed an 8000-cp. lamp to light the stopes and other workings. The Stewart Mining Co.'s gross earnings in February were \$157,000 and net profit \$112,000, as compared with \$64,600 and \$25,300 a year ago.

The Snowstorm Mining Co. has bought a controlling interest in the Missoula Copper Co. at a cost of about \$300,000. The two mines are 1¼ miles distant from one another. Charles E. Mallette, of Spokane, and Leo Greenough of the Snowstorm put the deal through.

MICHIGAN

HOUGHTON COUNTY

Considerable interest is being taken in the future treatment of 11,000,000 tons of tailing of the Tamarack company. This is said to average about 12½ lb. of copper per ton, and by grinding, about 9 lb. will be recovered. The mine is still shut down. From the Quincy 'rock' shipments are nearly 3500 tons per day. The Company will install the 'Baby Leyner' 90-lb. one-man drill in place of the old machines. There are 60 at work now and 40 more will arrive soon. The Hancock is producing 150 tons of rock, Superior 600 tons, and the Copper Range three mines from 3800 to 4000 tons per day.

MISSOURI

JASPER COUNTY

Production of zinc and lead ores from the district during the first nine weeks of 1914 was as follows:

| Ores | Tons. | Av. per ton. |
|----------------|--------|--------------|
| Blende | 44,082 | \$39.15 |
| Calamine | 2,754 | 20.98 |
| Lead | 7,628 | 49.57 |

MONTANA

MADISON COUNTY

(Special Correspondence.)—In connection with the news in this journal of February 7, of the option being taken on 20,000 acres of land near Twin Bridges, this option is to the El Oro Dredging Co. of Oroville, California. The area is about 3 by 12 miles. Land worth under \$25 for agricultural purposes is under option for \$100 per acre. Hence much joy among farmers of the district.

Twin Bridges, March 1.

SILVERBOW COUNTY

The overhead tramway from the Belmont shaft to the new steel ore-bins is ready for operation.

(Special Correspondence.)—The Anaconda Copper Mining Co. is more actively prospecting new ground now than at any time in its history. In the old silver district, west of Butte, it is unwatering the Nettle shaft, and preparing to sink deeper. East of Butte it has been sinking the Tropic shaft

and is to sink the Ella shaft on the recently acquired property of the Reins Copper Co. It is satisfying from an economic standpoint to reflect that money which formerly had to be spent in expensive wasteful mine litigation can now be put into new development. The new slime concentrating plant and the proposed leaching plant for the Anaconda smelter will mean increased population for Anaconda in the near future. Everything points to a gradual concentration of the Company's metallurgical activities at this place. The tonnage to go to Anaconda is to be materially increased, and the additional railway equipment to handle the increased tonnage on the Butte, Anaconda & Pacific railway has been ordered.

W. H. Weed's report on the Butte-Duluth, acquired by the American Metal Co., shows that 5,000,000 tons of ore has been proved by drill holes. He estimates the cost of mining and leaching 1000 tons per day at \$2 per ton.

Butte, March 1.

NEVADA

HUMBOLDT COUNTY

The first annual report of the Rochester Mines Co. shows that 14,726 tons of ore was shipped, worth \$368,770. Costs totaled \$25.04, of which lessees got \$9.79 per ton. The net profit was \$19,192. Development covered the following: trenches and open-cuts, 8160; cross-cuts, 1792; drifts, 2441; shafts, 634; raises, 730; and winzes, 165 ft. The president, J. F. Nenzel, urges the amalgamation with adjoining properties and the erection of a mill. There seems to be considerable local dissatisfaction with the control of this property.

The Seven Troughs Coalition Mining Co.'s mill is treating high-grade ore from the new shoot below No. 10 level. A canvas table has been installed to save the fine mineral which escapes from the concentrators. At 140 ft. in No. 4 winze there is 18 in. of \$594 ore. From 40 to 50 men will be employed by the end of this month.

LYON COUNTY

The Mason Valley smelter received 3556 tons of ore during the week ended March 4. Three cars of blister copper were shipped.

NYE COUNTY

The new gold and silver camp in the southeastern part of the county, discovered by Pat McAuliffe, has been named Blackthorn. It is 25 miles east of Goldfield and 3 miles west of Antelope, where is the nearest water. Prospectors are meeting with encouraging results.

The mines at Tonopah produced 10,162 tons of ore worth \$251,135 during the week ended March 7.

WHITE PINE COUNTY

An old stack, formerly used for the roasting furnaces at the McGill smelter, got into bad order until it was only 191 ft. high. It weighed about 9000 tons. On March 1, 14 holes were drilled into the base of the stack and 500 lb. of 40% dynamite exploded by electric current, and the structure demolished in good style. J. D. Watson and C. Anderson were in charge of the job. Two more McDougall roasting furnaces have been built, each of 80-ton capacity per day of concentrate. This department can treat 1440 tons per day. The last pay for 1500 men at McGill, 550 at Copper Flat, and 250 at the Veteran amounted to \$150,000, \$60,000, and \$30,000 respectively.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Oaks Co.'s adit 'A' has entered milling ore. Other parts of the property are giving good results. At 900 ft. in the Socorro, 7 ft. of ore is being mined, and 180 tons milled daily. This shoot has been persistent for 1400 ft. below the apex of the vein on the incline. The Maud's shaft is 700 ft. deep. No. 3 level in the Deadwood has cut the south orebody. The mill is working full time. The Pacific shaft is 70 ft. below No. 3 level, where the vein

is 7 ft. wide assaying \$14 per ton. Some rich ore is being mined from a 10-ft. stope below the 250-ft. level. About 35 tons is shipped per day to the custom mill.

Mogollon, February 23.

OREGON

BAKER COUNTY

A suit was recently brought by a number of farmers on Rock creek, who alleged that 'refuse and chemicals' discharged into the stream from the Highland mine made the water unfit for drinking purposes; also when the water was used for irrigation purposes a cement-like coating was left on the sides and bottoms of ditches, which eventually killed all vegetation. A temporary restraining order was granted several weeks ago, and the farmers are now trying to have the order made permanent. The Baker Commercial Club had almost arbitrated satisfactorily, when a difference arose, and the case went to the circuit court, Judge Anderson presiding. He has now made a permanent restraining order against the Highland company, which will not be allowed to pollute Rock and Maxwell creeks. This can be done without much inconvenience, according to the court.

TEXAS

BRAZORIA COUNTY

(Special Correspondence.)—A new electric power-plant is to be erected at the Freeport Sulphur Co.'s mines at Bryan Heights, and will also supply the town of Freeport. A new superheated water plant is also to be installed at the mines. The electric plant will consist of a 200-kw. Westinghouse steam turbine direct connected to a generator. Power will be used for pumping water from the canal, fuel oil from storage tanks on the ship canal to the mines, the machine shop, and all purposes in Freeport. The station will be installed by the Westinghouse, Church Kerr & Co. of New York, in connection with the other new \$125,000 equipment now being put in at the mines by the sulphur company. The new sulphur conveyor and loading devices installed by the Company at the Seaboard & Gulf Steamship pier on the Freeport ship channel, which has a capacity of 3600 tons per day for loading vessels with sulphur, is now completed, and ready for operation. It is expected that the first shipload of sulphur to be loaded and shipped from this port, will leave here on one of the Seaboard & Gulf Steamship Co.'s boats within a few weeks. A new loading equipment for handling this product at the mines has also recently been installed and is now in operation. It consists of a Brown hoist, with a loading capacity of 30 carloads of sulphur per day. With a railroad at the mines, and loading equipment at both the mines and at tidewater now built and in operation, the shipment of considerable tonnage of sulphur from Texas' only sulphur mines is expected for 1914. The present daily output is 200 tons of sulphur.

Freeport, February 21

UTAH

JUAB COUNTY

The Eagle & Blue Bell company will pay 5c. per share on April 1, amounting to \$44,657. Since the beginning of 1913, the total dividends are \$223,286.

SUMMIT COUNTY

The state of Utah is building a new capitol at Salt Lake City, and for a colonnade there will be 52 monoliths 31½ ft. high, 47 in. diameter, weighing 30 tons each. It was decided to use Utah granite and a contract was let to the Consolidated Stone Co. for 165,000 cu. ft., costing \$610,000. This Company has a quarry at Wasatch in the Little Cottonwood cañon. The monoliths were to be 11 pieces each, but this quarry can supply them in single pieces. A recent blast brought down 300,000 cu. ft. of granite, more than twice the amount required for the capitol's outside walls and monoliths. One piece was 46 by 54 by 98 ft. in dimension. A spur line is

being laid to the quarry, also a 50-ton crane and planing machine are to be installed. It is estimated that a finished monolith can be produced each week.

The annual report of the Silver King Consolidated Mining Co. shows that dividends in 1913 totaled \$308,791. Cash assets stand at \$384,859. Practically all litigation is ended. In sinking the shaft 500 ft. to the 1800-ft. level, the cost was \$46,700. Development during the 3½ months ended February 25, 1914, covered 2280 feet. From 1537 ft. of work near the shaft 1326 tons of \$41.34 ore was mined, also 2100 tons of 10 oz. silver, 5% lead, and some gold and copper ore.

As mentioned in this journal of last week, the Grasselli zinc plant near Park City has changed ownership, and under the management of George H. Scibird, the mill will be overhauled to receive custom ores from the district. Local capital is to finance the concern.

The Snake Creek tunnel was driven 275 ft. in February, and is now in 7000 feet. The flow of water is about 5500 gal. per minute. At present, with two shifts, 12 to 14 ft. per day is the advance, the face being fairly dry and requiring no timbering.

UTAH COUNTY

Assays of ore from the Santaquin King recently gave from 4.7 to 20.6 oz. silver and 40.5 to 70.9% lead. A block of ore containing 8000 tons of \$30 to \$35 ore is being prepared for mining.

WASHINGTON

Mining companies operating in the Coeur d'Alene of Idaho, and in British Columbia, and contiguous to Spokane, will pay the following dividends in March: Granby, \$225,000; Federal, \$180,000; Stewart, \$154,795; Hercules, \$100,000; Consolidated, \$116,088; Bunker Hill, \$81,750; Standard, \$50,000; International Coke, \$30,000; and Hecla, \$20,000; a total of \$957,638.

KITITAS COUNTY

(Special Correspondence.)—Ore has been opened in the old Bigney placer claim, at Liberty, which was recently acquired by William Johnson. It was supposed to have been worked out, but during the past two weeks three men have averaged about \$50 per day. The gold is mostly coarse, one nugget being worth \$43. The Bigney claim was famous as a producer about 12 years ago, when it produced over \$200,000. The recent discovery was made on the south channel, and will mean a general revival of work along Williams creek, where there are some good claims. Martin Meagher, owner of the Fraction claim adjoining the Bigney, has arrived here. He has some men prospecting the ground south of the old workings. Jack Stuart is sinking an incline in his claim, but bedrock has not been reached yet. He reports fair prospects in the blue gravel. There is considerable good placer ground here which has been scarcely worked at all, on account of lack of drainage. The Williams Creek claim-owners have been successful because they cut a drain through seven claims. These produced about \$600,000. Claim-owners on Lyons creek, which empties into Williams creek, are figuring on joining the Williams drain about half way, and so drain their properties, which, if done, will likely open some valuable ground. Prospecting on Lyons creek has been encouraging, and nuggets worth \$30 have been found. In prospecting the Beckman placer, owned by Mrs. A. Robinson, a good deal of fine and some coarse gold has been found. E. M. Wells has installed a gas-engine, pump, and hoist on his placer claim. Mr. McCauley, of Ellensburg, has bought a half interest in the Taft quartz claim from Amos Jordan Liberty, February 15.

Placer mining near Liberty is at times yielding nuggets worth from \$32 to \$62. Livingston Bros., M. Enecks, Nelson and Stevens, and Powers and Sugars are all busy at their claims. The latter are now sluicing. Johnson recovered \$126 from 7 yd. of pay.

Personal

P. R. BRADLEY will leave for Juneau this week.

EDMUND JUSSSEN was at Coulterville last week.

HOWARD D. SMITH was at Santa Barbara Monday.

SUMNER S. SMITH has left Juneau for Chisana and Fairbanks.

C. T. HUTCHINSON has been visiting the oilfields of California.

D. M. FIELD is with the Rio Arriba Co., at Tusas, New Mexico.

H. W. REED has returned to Salt Lake City from Long Beach, California.

GUY A. R. LEWINGTON has gone into the oil business, and will not return to Dawson.

ARTHUR L. WALKER has returned to New York from the South, having recovered his health.

JAMES IRVING has just returned to Los Angeles from a week's trip through Mohave county, Arizona.

L. F. S. HOLLAND is examining mines in Arizona and expects to return to Los Angeles about March 21.

F. H. HATCH is in the Kirkland Lake district, Ontario, where he is inspecting the Tough-Oakes mine.

A. W. STICKNEY, of Cambridge, Massachusetts, has gone to Kyshtimsky Zavod, Perm Government, Russia.

H. L. HUSTON has removed his office from the Mills to the Alaska Commercial building in San Francisco.

R. B. LAMB sailed on the *Lusitania* on March 11, for London, England, where he will remain for two months.

L. N. PARKS has been transferred from Jenny Lind to Yreka, where he is superintending the work of the Butte Dredging Company.

E. C. MORSE has resigned from the San Poil Consolidated Co., at Republic, Washington, and is at his home at Portland, Oregon.

J. S. ICKIS, field geologist for S. Pearson's Sons, Ltd., of London, is making a trip of observation through the Midway oilfields of California.

T. SKEWES SAUNDERS, superintendent of the Teziutlan Copper Co., Puebla, Mexico, has gone to England, as the property is shut down until the revolution ends.

A. W. GATES has retired as general manager for the Utah Ore Sampling Co., and intends to go into business at Salt Lake City; he is succeeded by F. M. Mansen, of Goldfield, Nevada, formerly associated with the Western Ore Purchasing Company.

Obituary

JAMES B. COOPER, superintendent of the smelting department of the Calumet & Hecla, died at Hubbell, Michigan, February 6. He had been in the service of the Company for many years and had been an important factor in building up the reputation of Lake copper for purity and uniformity of grade. Born within the limits of what is now Detroit, in 1859, he obtained his education in the public schools and the University of Rochester. His professional career included service in the old smelter at Hancock, Michigan, the Parrott plant at Bridgeport, Connecticut, and the Calumet & Hecla plants at Hubbell and Buffalo. His father, James R. Cooper, was a smelter before him and he grew up with a fondness for the art which led him to throw his whole energy into its development, and with notable success.

Schools and Colleges

The MASSACHUSETTS INSTITUTE OF TECHNOLOGY reports that Henry Tschetschott, professor at the St. Petersburg Mining Institute, is registered at the 'Tech' for special work. The Russian government requires teachers with a broad view for its schools, and is sending students to foreign colleges, in case of mining.

The COLORADO SCHOOL OF MINES, at Golden, will open a course on coal mining, for the benefit of coal mine employees, on April 1, ending on May 27. It will cover mathematics, mechanics and drawing, chemistry, geology, and mining. There will be no fees for instruction, only text books and material consumed will be charged, the total expense being about \$5. Wm. G. Haldane is acting president.

| Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, March 12.—The metal market is dull. Copper is still dropping and is weak at 14 cents. Greene Cananea February yield was 2,282,000 pounds. The British Columbia Copper Co. shows a deficit of \$442,600 for 1913, after paying dividends. Lead shows practically no change for five weeks and is quiet; so is spelter, which is a trifle lower than last week. Prices at St. Louis are 3.90 and 5.15c., respectively. London prices are copper, £63 15s. to £64 5s.; lead, £20; spelter, £21 10s.; and tin, £173 10s. to £175 7s. 6d. Tin in New York is 37.85 to 38.62 1/2c. Bar silver in London and New York is 26 3/8d. and 58 1/2c., respectively. Gold in London was up to 77s.9 3/4d. per ounce standard last week, the highest for 3 1/2 years.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-10c. per lb. more. Prices are in cents per pound.

| Date | Average week ending | 1913 | 1914 |
|-------------------|---------------------|-------------|------|
| Jan. 5 | 14.10 | 14.35 | |
| " 6 | 14.10 | 14.59 | |
| " 7 | 14.05 | 14.64 | |
| " 8 Sunday | | 14.55 | |
| " 9 | 14.00 | 14.34 | |
| " 10 | 14.00 | 14.22 | |
| " 11 | 14.00 | 14.04 | |
| Monthly averages. | | | |
| Jan. | 1913. 14.10 | 1914. 14.24 | |
| Feb. | 14.07 | 15.42 | |
| Mch. | 14.17 | 16.23 | |
| Apr. | 14.10 | 16.31 | |
| May | 15.10 | 16.08 | |
| June | 14.17 | 14.25 | |

Buying in the New York market was light last week and the metal sagged nearly a cent per pound. Exports during the last two days of February were unusually large and will bring the total for the month to over 77,000,000 lb. The

visible copper supply in England, France, and afloat there to March 1 was 18,559 tons, an increase of 1329 tons in the past fortnight; visible supplies at Rotterdam, Hamburg, and Bremen on March 1 were 8423 tons, a decrease of 198 tons since February 16; supplies at Rotterdam decreased 100 tons, at Hamburg decreased 91 tons, at Bremen 7 tons. Consumers here evidently expect prices to go lower, while the agencies are still hopeful of a better market soon.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | Feb. 26 | 1913 | 1914 |
|-------------------|-------------|-------------|-------------|
| Feb. 12 | 39.00 | | |
| " 19 | 39.00 | | |

| June | 45.10 | | Dec. 40.57 | |

COPPER PRODUCERS' ASSOCIATION REPORT

The Copper Producers' Association statement, March 9, shows a decrease in production and stocks on hand. The details are as follows:

| | Pounds |
|--|------------|
| Stocks of marketable copper of all kinds on hand at all points in the United States, February 10, 1914 | 87,206.68 |
| Production of marketable copper in the United States from all domestic and foreign sources during February | 122,561.00 |
| Deliveries for consumption, February | 47,589.65 |
| Deliveries for export, February | 83,999.18 |
| Stock of marketable copper of all kinds on hand and at all points in the U. S. March 2, 1914 | 78,711.87 |
| Recent changes in stocks have been as follows, in pounds: | |
| | Increase. |
| February 1913 | 800,137 |
| March | 18,022.42 |
| April | 28,720,162 |
| May | 8,074,888 |
| June | 14,569,679 |
| July | 600,000 |
| August | 5,280,908 |
| September | 8,531,043 |
| October | 17,111.88 |
| November | 1,361,994 |
| December | 3,009,138 |
| January 1914 | 4,142,182 |
| February | 8,924,833 |

Production of Spelter in the United States

The final figures of the United States Geological Survey for the year 1913, collected by C. E. Siebenthal, are as below, all quantities being stated in tons of 2000 lb.

PRODUCTION OF PRIMARY SPELTER¹ IN THE UNITED STATES,

APPORTIONED ACCORDING TO SOURCE OF ORE

| United States: | 1912. | 1913. |
|---------------------|---------|---------|
| Arizona..... | 4,092 | 3,152 |
| Arkansas..... | 604 | 478 |
| California..... | 1,672 | 2,535 |

| Grand total..... | 338,806 | 346,676 |

APPORTIONED ACCORDING TO LOCALITY IN WHICH SMELTED

| | | |
|--------------------|---------|---------|
| Illinois | 88,397 | 106,654 |
| Kansas | 101,104 | 74,106 |
| Oklahoma | 76,925 | 83,214 |
| Other states | 72,380 | 82,702 |
| Total | 338,806 | 346,676 |

'Primary spelter is made directly from ore, but secondary spelter is recovered from such sources as drosses, skimmings, and old metals.

The statistics, representing final figures, show production of primary spelter in the United States amounting to 346,676 tons, an increase of 7870 tons, or 2.3%, over the corresponding figures for 1912. At the same time the American consumption increased 13.2%, while the world's production only grew 3.1%. The preliminary estimates furnished by the Survey and printed in the *Mining and Scientific Press* for January 3, were within one-third of one per cent of these final figures.

PRODUCTION OF SECONDARY ZINC IN THE UNITED STATES

| | 1912. | 1913. |
|--|--------|--------|
| Secondary spelter, redistilled | 26,064 | 26,491 |
| Secondary spelter, remelted | 26,187 | 23,000 |
| Recovered zinc in alloys, excluding old brass remelted | 3,912 | 23,600 |

'Subject to final revision.

WORLD'S PRODUCTION OF SPELTER

| Locality in which smelted: | 1912. | 1913. |
|----------------------------|---------|---------|
| Australia | 2,531 | 4,105 |
| Austria and Italy | 21,609 | 23,856 |
| Belgium | 220,678 | 217,941 |
| France and Spain..... | 79,543 | 78,293 |
| Germany | 298,794 | 311,914 |
| Great Britain | 63,086 | 65,201 |
| Holland | 26,380 | 26,813 |
| Norway | 8,959 | 19,040 |
| Poland | 9,659 | 9,520 |
| United States | 338,806 | 346,676 |

| | | |
|---|-----------|-----------|
| Total | 1,070,045 | 1,103,359 |
| United States' percentage of world's production | 31.7 | 31.4 |

'Subject to final revision.

CONSUMPTION OF PRIMARY SPELTER IN THE UNITED STATES

| | | |
|----------------------------|---------|---------|
| Supply: | | |
| Stock, Jan. 1— | 1912. | 1913. |
| In bonded warehouses | 32 | 48 |
| At smelters | 9,049 | 4,474 |
| Production— | | |
| From domestic ore..... | 323,907 | 337,252 |
| From foreign ore..... | 14,899 | 9,424 |
| Imports | 11,115 | 6,100 |

| | | |
|-------------------------------------|---------|---------|
| Total available | 359,002 | 357,298 |
| Withdrawn: | | |
| Exports, foreign, from warehouse... | 6,286 | 6,027 |
| Exports, foreign, under drawback... | 1,188 | 7,459 |
| Exports, domestic | 6,634 | 7,783 |
| Stock, Dec. 31— | | |
| In bonded warehouses | 48 | |
| At smelters | 4,474 | 40,659 |
| Total withdrawn | 18,383 | 61,928 |

Apparent consumption 340,372 295,370

Imports and exports of spelter are given under the heading 'Consumption.' The imports of spelter in 1909-1913 are as given in the December Summary of the Bureau of Foreign and Domestic Commerce except that for 1909-1912 inclusive

the quantities given therein have been diminished by the quantity of zinc dust imported since August 6, 1909, for the reason that the imports of spelter and zinc dust were not separated in the Summary. The imports of spelter are also exclusive of sheet zinc. The stock in bonded warehouses does not include zinc ore in bond or the spelter made therefrom, such spelter being included in stock at smelters.

IMPORTS OF ZINC ORE, 1904-1913

| | Canada— Zinc Ore. | content. | Mexico— Zinc Ore. | content. | Total— Zinc Ore. | content. |
|------------|-------------------------|----------|-------------------------|----------|------------------------|----------|
| 1904 | | | 2,264 | | 2,264 | |
| 1905 | 4,063 | | 18,074 | | 22,137 | |
| 1906 | 423 | | 59,991 | | 55,414 | |
| 1907 | 1,112 | | 102,005 | | 103,117 | |
| 1908 | 7,406 | | 46,351 | | 53,757 | |
| 1909 | 10,024 | | 104,826 | | 114,850 | |
| 1910 | 4,749 | 1,922 | 67,818 | 23,517 | 72,626 | 25,439 |
| 1911 | 2,359 | 947 | 36,847 | 14,986 | 39,116 | 15,933 |
| 1912 | 8,015 | 3,661 | 35,925 | 14,206 | 43,940 | 17,567 |
| 1913 | 8,357 | 3,280 | 18,018 | 6,377 | 31,416 | 13,497 |

'Includes also 3232 tons of ore from Europe, containing 2440 tons of zinc, and 1792 tons from Siberia, containing 1397 tons of zinc.

Exports of domestic zinc ore in 1912 amounted to 23,349 tons and to 17,713 in 1913. Imports for the two years were as follows: 1912—Canada, ore 8015, zinc content 3661; Mexico, ore 35,925, zinc content 14,206; total, 43,940 tons ore, 17,567 tons zinc content. 1913—Canada, 8357 ore, 3280 zinc content; Mexico, 18,018 ore, 6377 zinc content; totals, 31,416 and 13,497.

Metal Output of the Daly-Judge Mine

This property is at Park City, Utah, and in 1913, 4954 tons of ore was sold, and 48,943 tons concentrated, with the following results:

| | Crude ore. | Concentrate. | Zinc middling. |
|---------------------------|------------|--------------|----------------|
| Tonnage of products... | 4954 | 11,909 | 3719 |
| Silver per ton, ounces... | 38.29 | 29.10 | 20.04 |
| Gold per ton, ounces... | 0.036 | 0.032 | 0.017 |
| Lead, per cent | 21.72 | 27.85 | 4.61 |
| Copper, per cent | 1.86 | 1.08 | |
| Zinc, per cent | 14.28 | 13.85 | 38.22 |
| Iron, per cent | 8.12 | 18.48 | 7.92 |
| Revenue, per ton | \$32.08 | \$29.91 | \$19.57 |
| Output. | | 1913. | To date. |
| Silver, ounces | | 611,378 | 4,457,506 |
| Gold, ounces | | 619 | 10,434 |
| Lead, pounds | | 9,128,078 | 95,971,888 |
| Zinc, pounds | | 7,678,589 | 69,323,069 |
| Copper, pounds | | 407,242 | 2,127,652 |
| Revenue | | \$588,940 | \$4,932,618 |

DIVIDENDS paid by the 'porphyry' copper mines to date are as follows:

| | |
|---------------------------|--------------|
| Chino | \$ 2,564,000 |
| Miami | 2,979,999 |
| Nevada Consolidated | 15,477,000 |
| Ray | 2,175,000 |
| Utah Copper | 22,217,000 |

SEVEN DREDGES are attacking the Cucaracha slide in the Culebra cut, Panama. The slide appears to be in slight motion right across to its farthest break, 1832 ft. from the canal centre line. About 1,500,000 cu. yd. or more will have to be removed before the slide ceases to menace the channel.

THE pig iron production of Belgium in 1913 amounted to 2,466,700 metric tons, as compared with 2,298,010 metric tons in 1912.

Recent Patents

1,974,234.—**ALLOY OF ZINC.** Thomas Abraham Bayliss, Warwick, England, assignor of one-half to Byron George Clark, London, England.

A malleable alloy composed of zinc, aluminum, and lead, in proportions between the limits of zinc 99.1%-99.9%; aluminum 0.001%-0.9%; and lead 0.01%-0.9%.

1,974,282.—**APPARATUS FOR THE TREATMENT OF ORES.** George Mitchell, Los Angeles, Cal.

In a combined smelting and converting furnace, the combination of an elongated furnace chamber having a smelting hearth therein and an opening in its bottom adjacent the hearth, a removable converter section and means carried by the truck for lifting and lowering and tilting said converter section.

1,974,410.—**AMALGAMATOR.** Lloyd Oscar Crocker, Beatrice, Neb.

An amalgamator comprising a rim provided with an annular compartment having a cross section bounded by an involute curve, a revoluble table carrying said rim and extending into said compartment, said revoluble table being in the form of a plane substantially tangential to a portion of greatest curvature of said wall, means for turning said rim and said table, and mechanism for discharging ore and water upon said table.

1,974,274.—**APPARATUS FOR EXTRACTING METALS FROM ORES.** Henry S. MacKay, Riverside, Cal., assignor to MacKay Copper Process Co., Riverside, Cal., a corporation of Arizona.

In an apparatus for the extraction of metal from ore the combination of two electrolyzing vats having anode and cathode compartments for containing the electrodes and fluids, the anode and cathode compartments of one vat being connected with the same compartments of the other vat, means for mixing the fluids produced in the anode compartments of the said vats, a leaching means to bring the ore and the said mixed fluids into contact, a third precipitating vat adapted to receive the solution from the said leaching means.

1,974,400.—**PROCESS FOR TREATING PEAT, SLIME, AND LIKE SUBSTANCES.** Gustav Wolters, Weltmar, near Bochum, Germany.

A process of treating peat, slime, and like vegetable substances of a high degree of humidity, consisting in forcing the substance into a chamber, comprising a plurality of communicating compartments, passing the substances successively from one compartment to another through said chamber, supplying heat to the off-take end of said chamber, and causing the vapors generated in the chamber from the substance to pass successively from one compartment to the other through the substance toward the intake end of the chamber, the pressure and temperature in the successive compartments increasing toward the off-take end of the chamber.

1,974,218.—**FUSE DEVICE.** Albert E. Simmons, Sacramento, Cal.

A fuse device of the character described, comprising a substantially vertically arranged outer casing, formed of insulating material, metallic conductor elements connected with the upper and lower ends of the outer casing, a fuse wire disposed within the outer casing, means electrically connecting the fuse wire with the upper metallic conductor element, a gravity operated rod connected with the lower end of the fuse wire, means electrically connecting the gravity operated rod with the lower metallic conductor element, and a cap disposed exteriorly of and adjacent the lower end of the outer casing and detachably connected with the gravity operated rod to drop with the same when it is released.

Industrial Progress

The NATIONAL TUBE CO. is now ready to distribute the booklet on 'N. T. C. Regrinding Valves' announced some months since.

The A. S. CAMERON STEAM PUMP WORKS announces the opening of a branch office and warehouse in the city of Philadelphia, Commercial Trust Building, under the management of Phil Weiss.

THE ELECTRIC WEIGHING CO. has issued a brief description of the special applications of electric conveyor scales (Messiter patents) to automatic tonnage control and automatic mixing.

THE HARDINGE CONICAL MILL CO. announces that its London office, which has now been opened just one year, received in its twelfth month orders for nine 'Hardinge Conical Mills,' for shipment into Russia alone.

The WESTERN ELECTRIC CO. reports sales for 1913 amounting to \$78,000,000, equivalent to an increase of 8% over the business in 1912. As telephones and telephone supplies go to all classes of people this is a good index to the general business of the country.

HEALDS ENGINEERING SCHOOL has added to its working equipment a complete working model for fine grinding and cyanidation of gold and silver ores. Among other apparatus included may be mentioned a Butters filter, Pachuca agitators, and vacuum and pressure pumps as needed.

GEORGE A. GALLINGER, of Pittsburgh, has been placed in charge of the Pneumatic Tool Department of the Ingersoll-Rand Co. with the title of Manager of Pneumatic Tool Sales. His headquarters will be at 11 Broadway, New York City. After an experience of 12 years in developing a general line of pneumatic tools the Ingersoll-Rand Co. felt warranted in establishing this special department. Mr. Gallinger's time and service are at the disposal of those contemplating the use of pneumatic tools.

HARRON, RICKARD & McCONE announce that at the meeting of the stockholders held February 8, the following officers of the corporation were elected: H. L. Terwilliger, president; H. G. Mitchell, first vice president; George O. Orr, secretary; E. H. Law, assistant secretary. The new president Mr. Terwilliger has been a member of the firm for several years and is advanced from the position of first vice president to that left vacant by the death of Mr. Harron. The business will be conducted along the same lines as before.

A NON-SKIMMING CRUCIBLE

The illustration herewith will show a new crucible which has been evolved by Henry Weisbrodt, an employee of the Joseph Dixon Crucible Co., to be used by melters of precious metals. It has been designed to do away with skimming, and also the possible chance of charcoal or molten fluxes getting into the ingot or casting. This crucible has a bridge at the top, which, on pouring the metal, holds back the charcoal and foreign matter, and so delivers clean metal. This new design does not in any way reduce the holding capacity of the crucible, and the metal can be stirred satisfactorily as in a regular crucible.

EDITORIAL

TROUBLE is brewing for the smeltersmen in Utah since the radical element has captured the Farmers' Association, and filing of additional damage suits is threatened.

A NEW argument advanced by an enthusiastic land boomer is that fruit-growers in a certain area are absolutely protected from scale by the fumes from a neighboring smelter. This illustrates the importance of the point of view.

THE Colorado Supreme Court has handed down a decision to the effect that assessors in determining the gross output of a mine shall deduct transportation and treatment charges. In Colorado, for purposes of taxation, mines are valued at 50 per cent of the gross output, plus all the net. In addition the value of site and equipment are taken into account.

FIGURES collected by the Customs Service show that in 1913 more people came out of Alaska than went into the territory, the departures being 25,798 and the arrivals 24,672. This is likely to be the last year that the current runs outward, since the building of the railroads, already authorized by Congress, and the opening of the reserved lands seems certain to lead to rapid and substantial development.

A CORRECTION is called for in regard to the description of the battery frame adopted at the Tightner mine and described in our columns March 7. This was inadvertently stated to be made of cast steel in place of cast iron. The latter material was purposely chosen, since weight and stiffness were desired rather than strength. There are no great strains on the posts, though vibration is naturally important. Weight and rigidity are therefore more important than toughness.

IN accordance with our plan of publishing reviews of the year's work in various countries at the time that reliable data are available, we print this week a summary of mining in Peru in 1913, written by Mr. Lester W. Strauss, a practising engineer living at Lima and thoroughly acquainted with the matters of which he writes, by first-hand information. Mr. Strauss is just now visiting various mining districts in Chile, and we shall present later notes and comments upon mining in that country as seen by him.

SETTLEMENT out of court has been effected in the suit of the Merrill Metallurgical Company against the Ajax Mining Company for infringement of patent rights in connection with the use of zinc dust for precipitation. Mr. E. A. Colburn has published a letter stating that, having examined the patents involved, he is now satisfied as to the infringement and has therefore made settlement. The mill will operate hereafter under license from the Merrill company and will adopt some slight changes advised by the latter.

CALIFORNIA mine operators, manufacturers, transportation men, and employers of labor in many branches of trade, as well as representatives of laboring men, met the Industrial Accident Commission in a 'Safety First' conference at the Palace hotel on March 13. It was brought out that there were 823 deaths and 36,462 industrial accidents in the state in 1913, and that a considerable portion were preventable. The safety department now being organized by the Commission is charged with the duty of pointing out ways to decrease the number of accidents, and it was evident from the serious tone of those present at the conference that it will meet with wide and ready coöperation.

DECISION has been rendered in the United States Court of Appeals for the Third District, in the case of Tonopah Mining Company *versus* Joseph A. Vincent on appeal, involving the question of infringement of the Brown patents by the Tonopah company. The court held that, without passing upon the validity of the patent, it was sufficient to hold that the defendants do not infringe. The case was accordingly reversed and remanded to the lower court with instructions to dismiss the bill for non-infringement. Lack of space prevents printing the full text of the decision at this time, but in general it was held that use of concentrating as an intermediate process was in any event not an infringement of patents covering cyanidation followed by concentration.

WISCONSIN, which has led in so many political and educational reforms, is not unwilling to follow where the example is good. Some years ago the University of Illinois, impressed with the excellent results of the Agricultural Experiment Stations, organized an Engineering Experiment Station, which has been a large factor in the subsequent improvement in mining and manufacturing processes, and the general engineering work in that state. Similar stations have since been established elsewhere, and now the University of Wisconsin announces that all the work of testing and research along engineering lines conducted at the University will be consolidated under an Engineering Experiment Station staff. We are glad to see this emphasis placed on such work, as we believe thoroughly that it is as much the function of the University to teach the state as to teach the

citizens-to-be of the state, and that the best service of science and technology should be always available to the state government.

SENTENCES of six years in the federal penitentiary at Atlanta, Georgia, have been announced against Messrs. A. L. Wisner and John J. Meyers, found guilty of using the mails to defraud in connection with the sale of worthless mining and oil company stocks. It is an anomaly that in this country punishment is less commonly for fraud than for some such incidental matter as using the mails for fraudulent schemes. Welcome as the results are, it is a serious question whether the law does not become a joke when it is necessary to send dynamiters to prison for having conspired to transport dynamite on an interstate passenger train, because it is impossible to jail them for blowing up buildings and killing or attempting to kill men and women. To a layman it would look as if the prevalent custom of leaving law-making mainly to young lawyers who go to the legislature as a polite and ethical form of advertising, has its drawbacks.

Zinc Ore in the Electric Furnace

This is a subject on which there has been much experimental work and even more discussion, and it is but fair to say that the attitude of mind of most of the metallurgical fraternity is distinctly skeptical of immediate or even remote success. Recently Mr. W. McA. Johnson has claimed to have succeeded in putting zinc smelting in the electric furnace upon a practicable basis, and as a consequence keen interest has been taken in the results being secured in his experimental plant at Hartford, Connecticut. In January about 17 tons of zinc ore from Colorado was there smelted and the records have been given wide publicity. They are interesting enough to justify closer analysis, however, since they are by far the most significant data on electric zinc smelting which have yet been made public. The best results, covering a period of seven days, correspond to a recovery of 88.4 per cent of the zinc present, with a power consumption of approximately 2.7 kilowatt-hours per pound of spelter produced. The power consumption, however, should be credited with the base bullion and the copper in the matte produced, and on this basis the power consumption was about 2.2 kilowatt-hours per pound of metal. It should be noted in this connection that the blue powder and skimmings produced are charged back into the same furnace without any record of their weight affecting the data, so that the figures for power consumption are actual, not fictitious figures which take no account of the re-treatment of by-products. The amount of cold seconds thus rehandled is about 20 per cent of the spelter produced. Electrode consumption is given as two to three pounds per ton of ore smelted.

The greatest care is required in the preparatory pre-heating in which the necessary reduction is effected

preceding the simple fusion in the electric furnace. This does not involve any novelties of practice, however, and should not cost over \$2 or \$3 per ton in commercial work. On the basis of cost, therefore, smelting in this way seems entirely practicable. Innumerable difficulties cannot possibly be foreseen until trial is made under actual working conditions, and it is therefore possible that this new method will not prove as successful as its advocates think, but the results so far attained are highly encouraging and of great interest.

Mining Law Revision

Bills have been introduced in both the Senate and the House at Washington providing for opening to entry the withdrawn lands supposed to contain coal, petroleum, potash, and phosphate. The area affected amounts to 323,000,000 acres in addition to lands in the National Forests and Alaska. A special act covering the Alaska coal lands is already under consideration. The bills introduced are considered to be Administration measures, and follow the lines proposed by Mr. Franklin K. Lane in his annual report, which we have already discussed. In general they provide for a leasing system, the ground to be allotted in blocks materially larger than under the old fee basis, and in the case of oil with exclusive prospecting permits and other advantages to those who undertake development of new territory. We are glad to see some definite steps taken toward opening the reserved lands, and the general lines of the policy proposed have our hearty approval. The new law will not apply to mineral lands in general, and it will still be necessary to get a general revision of the mining law. Clearly, lands which show such evidence of the presence of coal, oil, potash, phosphate, or other minerals as to warrant their withdrawal, stand in a different category from the public domain in general and in which the presence or absence of mineral cannot be positively known in advance of prospecting.

There is perhaps reason for framing a separate law to govern such lands, but the more important matter is the general revision of the mining law proposed in Senate bill 4373. Piecemeal revision has led to most of the difficulties of the past, as when the placer law was extended to cover oil lands regardless of the difference in the character of the deposits. A thorough and systematic revision of the mining law is needed, and, as we have pointed out, the new code should be prepared by men familiar both with the existing law and present practice in the field. It is, we think, entirely feasible to establish a leasing system such as outlined, and to apply it to withdrawn lands and non-metallic minerals, and still leave the old law largely intact, to cover the public domain in general. The old law, however, needs change in many important particulars, as has been pointed out by committees from the American Mining Congress, the Mining and Metallurgical Society, and the American Institute of

Mining Engineers. The needful step now is the constitution of a suitable code commission to hold hearings and report to Congress next year. This commission should include mining men as well as lawyers, and we urge those interested to impress this fact on their representatives at Washington.

Presentation of the M. and M. Medal

The presentation of the gold medal of the Mining and Metallurgical Society of America to Mr. and Mrs. H. C. Hoover was made at a dinner, March 9, at the Biltmore hotel, New York. Nearly one hundred members of the Society and Institute were present. Mr. J. F. Kemp, the president of the Society, was the toastmaster. Following the dinner, Mr. Kemp, in one of his characteristic happy speeches, emphasized that the presentation of the medal was to Mrs. Hoover as much as to Mr. Hoover, and that therefore the toast to the ladies should, for that evening, take precedence of all others. Mr. Sidney J. Jennings, responding to the toast, carried along the same vein of thought in a very graceful speech. Mr. T. B. Stearns was then called on and in an interesting talk emphasized the linking of the West and the East, in which Mr. and Mrs. Hoover are typical of the cosmopolitanism of the mining profession. Mr. Kemp then presented the medal, congratulating the Society, as well as the recipients, on the fact that the first medal of the Society was given for work of the highest scholarship, coming from a profession that is too much regarded as one of the most materialistic. Mr. Hoover, in responding, carried on the same line of thought, pointing out that miners have played a larger part in the development of civilization than is commonly awarded them, the mines of Greece having been largely responsible for the flowering of Greek civilization, and the self-governing mining communities of central Europe, Cornwall, and Derbyshire having been powerful influences in the development of representative government. After the dinner an opportunity was afforded to those present to see the medal, which has on its obverse a woman's figure, lighted by a miner's candlestick, engaged in breaking down a wall of rock which typifies ignorance and superstition. A most attractive feature of the dinner was the souvenir program, made up of illustrations so selected from 'De Re Metallica' as to illustrate the labors of Mr. and Mrs. Hoover in translating the book. From the first, marked 'Ye Hooverses jumpe ye antiquas of ye anciente manne Agricola,' to the last where 'Ye Hooverses menne refine ye golde and ye silver, ye Hoovere, himself, weigheth ye bullion, ye Hoovere will later putte ye bullion in ye bank for ye othere Hoovere to spende,' the selection was most happy. The program was compiled by Mr. E. G. Spilsbury, chairman of the dinner committee, to whom, with his assistants, Messrs. L. D. Huntoon and D. M. Riordan, a large share of the credit for a most successful and enjoyable evening are due.

Mining in Peru in 1913

By LESTER W. STRAUSS

The most important features in the mineral industry in Peru last year were the increase in oil production, and, to a lesser degree, of gold from the vein mines. No new business of magnitude was taken up, although increasing interest was displayed in the mineral possibilities, particularly as regards gold.

Copper Mines and Smelters

According to the statistics of Aron Hirsch & Sohn, the production was 27,500 tons (metric), as compared with 27,400 tons in 1912. (In 1903, 9500 tons was produced.) The year 1914 will mark the beginning of in-

fitted with three Stirling boilers to utilize the waste gases; the economy effected has shown a credit of about £1000 per month. The three Dwight-Lloyd sinterers have given splendid results and four additional machines will be put into commission; the average individual capacity on ores containing 22% sulphur is 80 tons per 24 hr., while with ores containing 40% sulphur the capacity decreases to 45 tons. The omission of lime in the ore fed, has tended toward slightly lower operating costs. The shortage of locally made coke decreased the smelting capacity, although in one month 35,000 tons of ore was treated. With the increased output from the Quishuarcancha coal mine, now averaging 250 tons per day since the railroad branch has been opened for traffic, the utilization of the waste gases from the reverberatories, and the introduction of electric power transmitted from the recently completed 12,000 hp. hydro-electric plant at Oroya (119 kilometres to the south), there will probably be no coal famine for the washing and coking plant at the smelter.

New Power Plant

The electric plant is said to have cost over \$1,000,000 erected. It is expected to reduce power costs, not only at the smelter and mines, but also for the Morococha Mining Co. (a subsidiary company of the Cerro de Pasco Mining Co.) at Morococha (25 kilometres westward from Oroya). The latter company contributed over 6000 tons monthly to the smelter, although the mines controlled are only at the developing stage at present. Surveys were made for a railroad line that

MAP OF CENTRAL PERU.

creased copper production, the result of the improvements in smelting capacity made by the Cerro de Pasco Mining Co. and the Baekus & Johnston Co., which concerns are responsible for 44,830,107 lb. and 10,341,120 lb. of copper, respectively, produced in 1913. The latter company shipped 8,071,000 lb. matte and 2,270,120 lb. ore. Several small smelting plants and mines contributed the remaining 5,428,793 pounds.

The Cerro de Pasco Mining Co. did not operate under full capacity, only three of the four blast-furnaces (which are now between 70 and 80 in. wide at the tuyeres) and three of the five reverberatories being in commission. Two Smith-Pierce basic lined converters are now in service; a third is to be installed soon. One of the reverberatory furnaces has been

CERRO DE PASCO SMELTER AT LA FUNDICION.

would tap the Cerro de Pasco railroad and avoid the present circuitous haul over the Central Railroad of Peru to Oroya, but no further steps were taken; it appears that the ruling grade was not favorable for the economies that were anticipated.

In addition to the Morococha tonnage, and that produced by its own mines, the Cerro de Pasco Mining

AREQUIPA, CHIEF CITY OF SOUTHERN PERU.

Co. purchased considerable custom ore; the Docena mine in Cerro de Pasco contributed about 200 tons per day; other outside properties did not ship as heavily.

After spending four years in reorganization and reconstruction, involving marked steps in the improvement of its treatment plant as well as mining operations, the Backus & Johnston Co. is meeting with profitable results. The foresight, energy, and ability of the late J. Howard Johnston (who was the president and largest shareholder of the Company at the time of his sudden death in May) are directly responsible for the rescue of the business from apparent bankruptcy. The £100,000 loan made early in the year, to cancel the obligation of a large creditor, is now being retired, the first £2000 bonds recalled having been paid on December 31. The smelter is essentially a silver-copper plant and produced 1,950,000 oz. of silver in 1913. The silver ores from the Casapalca mines, as well as the custom ores obtained in the region, are dependent in a measure upon the Morococha mines which supply the necessary iron, as well as copper and silver.

The new hydro-electric plant of 2000 hp. effective (6 kilometres below Casapalca, at Bellavista) has been in service since November. In consequence the converting plant, consisting of two stands of 96 by 150-in. barrel converters (capacity 30 tons of copper per 24 hours each) and Nordberg blowing engine, has been tried out with satisfactory results. The year 1914 will mark the production of blister copper; a shipment from the trial run has been exported. The new 160 by 52-in. blast-furnace was also blown in; the old one, after four years of hard service, having been put out of commission for necessary repairs and changes, will be blown in soon. The monthly smelting capacity will probably be about 12,000 tons of raw and sintered products. The sintering plant now consists of 29 pots and the success of these has made the smelting difficulties decidedly less worrisome. The concentrating mill

will be enlarged to handle 250 tons per day. The entire electric plant is not yet in use, but meanwhile all arrangements are being made to extend the line to the Company's Morococha properties and to replace the more expensive steam-power plants. Oil has been replacing coal as the fuel during the transition stage.

The Compañía Minera del Carmen and Compañía Minera de Huarochiri, operating in the Casapalca district, ship considerable argentiferous ores to the Backus & Johnston smelter. The former company is driving a long cross-cut, using electric drills, that is expected to cut the Carmen vein within 2200 metres. This will serve to explore the veins of the district at the lowest level attempted as yet. The latter company ships its high-grade ruby-silver ores to Europe, the lower grade being sent to the Casapalca smelter.

Morococha Mines

The Morococha district is attaining considerable importance as a producer, and will be a large factor in contributing to the copper, and to a lesser degree, to the silver production of Peru. The vigorous campaign of development planned by the two principal producers, the Backus & Johnston Co. and the Morococha Mining Co., has barely begun, yet the combined monthly output of the two companies under present conditions is over 12,000 tons, including the ore from

SMELTER AT CASAPALCA.

CALLAO HARBOR, PORT OF ENTRY FOR LIMA.

the numerous properties leased by the former company. Most of the custom ore shipped is sent to Casapalca. A small, privately controlled furnace is operating in the district, having sintering pots as an important feature, and ships about 50 to 60 tons of copper matte monthly to the Cerro de Pasco smelter; the source of ore is from small producers. The plant is undoubtedly the highest operating smelter in the world, being 15,000 ft. above sea-level.

E. E. Fernandini's smelter at Huaracaca, near the Cerro de Pasco plant, treats about 3000 tons of argentiferous ores with a low copper content (less than 2%), sufficient however to make matte that assays 1300 oz. silver and 50% copper. The silver ores come from the Colquijirca mine (close to the Cerro de Pasco smelter), which has been recently equipped with electric haulage and a 20-drill air-compressor. The copper ore is from the Cerro de Pasco mines of E. E. Fernandini. The production for the year was over 1,700,000 oz. silver and 1,100,000 lb. copper as matte.

Of the smaller producing copper mines the Sociedad Minera Quiruvilca, Ltd., in the Department of Libertad, is the most important shipper, averaging about 100 to 150 tons of 35% copper ore (with slight gold and silver content) per month, which goes to the United States. In the Department of Cajamarca, the Compañía Minera Sayapullo, Ltd., which is negotiating for the sale of its properties, has been smelting spasmodically in its 30-ton water-jacket furnace at the rate of ten tons of ore per day (anthracite coal is the fuel). The resulting matte (averaging 36% copper, 170 oz. silver, and 2 oz. gold) is shipped to Europe. The Company has thus been enabled to pay some old debts as well as the interest on its bonds.

Southward, in the Department of Ancash, the Empresa Minera San Juan, Ltd., of Tarica, is obtaining better results with its 15-ton smelter; the matte exported averages about 35% copper and 300 oz. silver, with a little gold. Anthracite coal is employed in smelting. In the same department, the Magistral properties, belonging to Garaborri y Compañía, have been optioned to local people who intend to develop the property. Anthracite coal has been used in past operations in the 30-ton brick furnace; the matte production has been small. At Vinchos, near Cerro de Pasco, the Yanamina Mining Co. has recently blown in a 30-ton furnace which will smelt copper and silver-lead ores; the matte will be shipped to Cerro de Pasco.

Of the properties that have been developed, the Ferrobamba mines were inactive the past year; the region was recently reported on by a commission from the Cuerpo de Ingenieros, which states that the average grade of mineral is under 4% copper. The French syndicate that purchased the properties, now known as the Sociedad Cuivre de Huaron, near Huailay (35 miles from Cerro de Pasco), has met with favorable results in development; over 100,000 tons of ore, said to average 12% copper, is in sight, but no shipments of ore are to be made as the erection of a smelting plant is under consideration. Coking coal is obtainable close by. Considerable exploration was done on the Cobriza copper claims, in the Province of Tayacaja, but no work has been carried on since May. The Empresa Minera de Huallanca, controlling silver-copper mines at Huallanca (125 miles northwest of Cerro de Pasco), has been optioned to a French syndicate.

Lack of adequate transport, and its high cost, handicaps the development of the copper possibilities of Peru. Under certain conditions local smelting could be made a profitable business.

Gold Ores and Mines

Much outside interest has been taken in the development of the gold industry, although this continues to be unimportant if no regard is taken of the gold derived from copper and, to a less degree, from lead ores. Activities in vein mining are increasing, although no large properties are in operation, while the placers are, as yet, smaller producers.

The largest producing property is that of the New Chuquitambo Gold Mines, Ltd., six miles below Cerro de Pasco. The production for the year ending November 1913, was 114.34 kg. (nearly 3700 oz.) of bullion (over 900 fine), which represents a recovery of 65% to 70% effected by amalgamation from the treatment of 80 to 100 tons of ore per day in the 40-stamp mill; 140 men are employed in the mine and mill. The cyanide plant, erected to treat the tailing that is being stacked up after leaving the amalgamation plates, no concentration being attempted, has been abandoned due to the small amount of copper present.

The Cotabambas Auraria, at Cochasayhuas, in the Department of Apurimac, has increased its production since the cyanide plant for coarse sand has been in operation. The December output was expected to be about £3000 of bullion. The present 10-stamp mill,

ATICO, PROPOSED HARBOR FOR THE FERROBAMBO MINE.

one Huntington mill, and two Ferrarris tables, treating 16 tons of sorted ore per day, is to be increased with 40 additional stamps and a cyanide plant of adequate capacity, so that 100 tons can be milled per 24 hours. An aerial tramway will probably be erected, and a vigorous development campaign on the veins will be commenced.

Another probable increasing producer is the Sociedad Aurifera Andaray Posco, in the Department of Arequipa. The present plant consists of two Lane mills. Only one is in operation and is said to handle 20 tons per day, the recovery by amalgamation (stated to be 50%) varying from £500 to £800 per month. The new cyanide plant, ordered as the result of tests which showed a 90% extraction, is expected to arrive in January and will treat from 40 to 60 tons per day.

In the Department of Puno, the Santo Domingo mine, of the Inca Mining Co., with a past record of £700,000 production, has been optioned to an Argentine syndicate for £120,000. Some development work is being carried on and the tailing dump of previous operations, said to contain over 50,000 tons, is being treated on a small scale. The Montebello property, distant six miles, has been optioned by the same people. Both properties may form the basis for the flotation of a new company. The Benditani property, adjoining the Santo Domingo mine, will be developed by the Sociedad Minera Benditani, Ltd.

Near Nazca, in the Department of Ica, a one-foot vein, averaging over 7 oz. gold and 5% copper, when sorted, is being developed; the property lacks water for milling. In the Potaz district, Department of Ancash, the Potaz-Parcoy Syndicate, Ltd. (now known as the Peruvian Consolidated Gold Trust, Ltd.), has been developing the several veins controlled; 100 men have been at work. In the Buldibuyo district, 15 miles away, some development is being carried on; a 3.5 ft. Hardinge ball mill has been erected to treat the oxide ores.

The production from the alluvial deposits is still small, disregarding that resulting from the native washings. The only company that has operated continuously and profitably is the Compañia Aurifera Argentina-Peruana, at Viscachani, Department of Puno. In the same province, the Aporoma Goldfields, Ltd., has not been as successful as was anticipated. On account of the lack of water, operations were very limited. About £25,000 is needed for an additional

ditch line, according to the Company's statements, that would permit bringing in sufficient water "to wash at least 10,000 cu. yd. per day." The 42,500 cu. yd. washed, during the initial working, showed a recovery of 7.3d. per cubic yard.

In the same vicinity a California syndicate has been investigating an extensive territory, upon which dredging operations are likely to be adopted if the preliminary work continues to be satisfactory; 30 tons of drilling machinery was taken to the field. The transport of dredge machinery will involve the building of a railroad. 'Pot hole' washing was attempted on a tributary of the Inambari river, with some success. A French syndicate is said to have taken an option on dredging ground in the Poto district. The Ambo Gold Mines Co., which was formed to exploit extensive alluvial ground on the Huallaga river, two days horseback ride from Cerro de Pasco, has been inactive since May as the result of an examination which indicated the value of the gravel to be \$0.45 per cu. yd., as compared with \$6 per cu. yd. in the earlier samplings. It is believed that gold chloride and shavings played an important role in the latter returns, having been presumably introduced when the samples were in transit from the property to the assayers. Recently a New York syndicate has formed the Peruvian Exploration Co., to exploit 1117 acres on the Marañon river (four days horseback ride from Cerro de Pasco); \$300,000 has been raised and it is expected that operations will commence by March 1915, using giants capable of handling 25,000 cu. yd. per day. The river will be diverted, in sections, to permit washing. There is stated to be 131,150,840 cu. yd. available, averaging \$0.809 per cu. yd. Near the Ecuador border investigations have been made for a London syndicate; this ground is said to be suitable for dredging. Native washings have been carried on for years in the region.

Silver Mining and Milling

The usual percentage of the silver exported is 'tied up' in blister copper, matte, and ores, also in lead bars, ores, and slags, and a small amount of silver ores of exceptional high content. The production of silver bullion from pan amalgamation and sulphides from lixiviation form a small percentage of the silver output. Cyaniding is not being done at any property, but the process will soon be adopted at Caylloma. Peru ranks sixth among the silver producing countries.

The most important silver property, other than those which ship argentiferous copper or lead products or ores, is the Sociedad Explotadora de Caylloma, in the Department of Arequipa. The work for the year was restricted to the development of the San Cristobal vein and the driving of a drainage adit for the mine, which will be nearly two kilometres in length; this is expected to be finished in March and make available considerable ore. In anticipation of this result a concentrating and cyaniding mill, of 100 tons capacity per day, will be erected and ready for operation early in 1915. The San Cristobal vein, which is the largest in the property, has been opened up for 300 metres, vertical depth, and averages 10 metres in width. The existing narrow gage railway between the mines and the mill, 12 kilometres long, will serve for the transport of the ore. During the year only the sorted ore from the development and preparatory work in the San Cristobal mine was exported, amounting to 250 tons containing 60,000 oz. of fine silver. No ore was milled, as the old concentrating mill was closed down. The Santa Inés mines, in the Department of Huancavelica, continued to produce silver bullion at the rate of 150,000 oz. per annum. The pan-amalgamation plant treats 20 tons of run-of-mine ore per day, the tailing being now stacked for future treatment. There are numerous lixiviating plants scattered over the country, but principally in the Departments of Junin and Ancashs, which contribute 10% of the total silver produced. Near Cerro de Pasco the patio process is still in vogue for the oxidized silver ores that are being extracted by the natives from the old Spanish open-cuts. The Anglo French Tiacapampa Silver Mining Co. in the district of Recuay, Department of Ancashs produces the largest amount of silver sulphides in Peru. This is treated by lixiviation. High-grade silver-copper ore is also shipped abroad.

Lead and Minor Metals

The lead industry continues unimportant as regards production, although the year will probably show the largest output, in view of the high price of the metal. The Yauli district, in the Department of Junin, is still the heaviest argentiferous lead ore exporter. There are two small lead furnaces, which ship lead bars containing much silver (over 1000 oz. per ton), in the Department of Ancashs—otherwise no lead smelting is carried on in Peru. Only one lead concentrating plant exists; this is on the Central Railroad of Peru close to the town of Yauli. Considerable lead slag, the remains of the early Spanish silver smelters, was exported.

The province of Pallasea, in the Department of Ancashs, is the only producing source of tungsten. Three companies are active, but two have not yet reached their anticipated production, because the milling plants are still uncompleted. The total monthly shipments are said to be 30 tons of concentrate averaging 60%. The San Gregorio property of E. E. Fernandini, near his smelter, is the only producer of bismuth. Shipments amounting to 200 tons of concentrate, averaging 20% bismuth, were made. The output is limited

by the trust. The exportations from the Minasragra deposits, of the American Vanadium Co. (30 miles from Cerro de Pasco), have been limited, because of the restriction of output. The interest displayed in coal containing vanadium has fallen off in view of the low prices quoted for the vanadiferous ash. The Santa Barbara mercury deposits, in the Department of Huancavelica, continue to be worked in a small way, the output being consumed at the Santa Inés plant and in the patio process near Cerro de Pasco. Deposits of tin of importance were reported to exist in the Departments of Lima and Libertad, but official or reliable confirmation is lacking.

Non-Metallic Minerals

Of the non-metallic products, petroleum occupies the first position. Coal production, as yet, is chiefly that from the Cerro de Pasco Co.'s mines, and is increasing. Borax will become an important product, according to the plans of the Borax Consolidated, Ltd. The exploration work of possible nitrate ground has not resulted in discovery of deposits likely to produce largely.

The oil industry, confined to northern Peru, continues to increase in production as well as importance; the output for 1913 will be over 2,000,000 bbl. Prices have been higher in view of the increasing appreciation of the high-grade benzine petroleum that is produced. The entry of the Standard Oil Co., as the controlling factor in the various companies, has brought the fields into more prominence. Drilling the deep sands, the wells being over 3000 ft. deep, has given profitable results in most cases. The Government continues to withhold oil lands from denouncement.

The coal industry is practically confined to the output of the Cerro de Pasco mines (for coke and power purposes), as lack of transport facilities prohibits shipments to the coast. Considerable coal and coke (about 100,000 tons) is imported annually. The Government has withdrawn several regions from denouncement, with the intention to interest foreign capital in the respective coals and thereby create a stimulus for building railroads.

The deposits of borax near Arequipa (in the department of that name), which are owned by the Borax Consolidated, Ltd., will be actively exploited in view of the concession granted by the Government, that exempts the product from any duty for 18 years, commencing from the date the Company begins to export at the rate of 20,000 metric tons of calcined borax. The export tax contemplated by the Chilean government on the calcined borax, may cause a decline of the operations of the Borax Consolidated, Ltd. in that country. Chile contributes 75% of the world's production. Investigations of supposed nitrate fields commenced in 1912, in the Department of Arequipa, were abandoned early in 1913, as the region examined did not cover nitrate of economic value. Mention has recently been made of a discovery of 500 acres of 9% nitrate ground in the Department of Libertad, but no data as to the tonnage are obtainable.

The Globe Mining District, Arizona*

By WILLIAM L. TAVOTE

Disseminated Sulphide Impregnations in Fracture Zones

The main representative of this type is the Miami-Inspiration deposit. It constituted apparently a single and continuous orebody at one time, later disrupted by faults. It consists of disseminated iron-copper sulphides in a brecciated zone of Pinal schist with intruded tongues of granite-porphry (Schultze granite). Its economic importance is at present limited to the horizon of secondary sulphide enrichment (chalcocite zone). The Miami Copper Co. holds the richest and thickest part of the orebody, but is exceeded in tonnage by the lower grade ore of the Inspiration company.

The Keystone has a smaller faulted part of the orebody between the Live Oak and Inspiration parts of the Inspiration Consolidated Copper Co.'s ground, and the Southwestern Miami is drilling on the western fringe and has reported chalcocite ore from several holes. Exact information is not given out, but it seems that the ore is capped by about 1000 ft. of overburden, and is rather low in grade. The total tonnage developed thus far is about 20,000,000 tons of 2½% ore for the Miami, 45,000,000 tons of 2% ore for the Inspiration, 2,500,000 tons of 2¼% ore for the Keystone, and perhaps 70,000,000 tons altogether. Still farther west the South Live Oak has reported ore in two holes out of a total of eight drilled, but it is not impossible that the ore reported occurred along steep and narrow veins rather than in a body similar to the Miami-Inspiration.

Claims to possibility for ore are put forward by the owners of the Barney, Needles, and Inspiration Extension groups, and hundreds of claims in the vicinity are held for good luck. It is rather difficult to delimit the possibilities from surface indications, as strong overthrust faults and recent covering by dacite and Gila conglomerate obliterate the original structure. Three holes were drilled on the Barney group while an option was held by the Miami people. The result was negative as far as can be learned and the option allowed to lapse. In this connection it is interesting to note how tremendously a piece of mountain side with no mineral whatever in sight increases in value simply by posting of location notices and making a few shallow cuts in Gila conglomerate or similarly promising formations, for the prices asked by the owners range from \$100,000 up to nearly \$1,000,000 for anything in what they consider to be in the 'schist-belt.'

A wonderful outcrop several miles farther west on Pinto creek inspired exploration work by the Caetus company. Some ore, at one time reported 2,500,000

tons, was found, but the Company collapsed and it is almost impossible to decide whether the failure was due to the physical condition of the property or to other reasons.

While prospecting has been carried on almost exclusively to the west of the Miami mine, the chances for an extension of the orebody to the southeast seem fair in my opinion, because the ore does not terminate by a gradual playing out, but is broken off by a fault close to its strongest development. The covering of Gila conglomerate on the downthrown side might possibly amount to several thousand feet, and as it stretches unbroken from here to Globe and the Pinals it is hardly attractive for exploration work aside from other factors that militate against it, such as water problems.

The Miami part of the district has been described several times, and rather exhaustively. Therefore I shall touch on it but briefly. The ore occurs as impregnations or in small interlinked veinlets in a zone of brecciated schist and porphyry. It is pyrite partly replaced by chalcocite. Sericite is a nearly constant accessory mineral. Kaolinization and sometimes chloritization has locally gone far. As sills of Schultze granite participate in the mineralization, it must be later or contemporaneous with that eruption. The surface indications are an intense reddish stain of iron oxide and sometimes a vivid green coloring by chrysocolla, but the local experience seems to be that the iron, rather than the copper stain marks the presence of ore.

Irregular Metasomatic Bodies of Secondary Ore

The Black-Warrior and Geneva mines work on orebodies that have been formed by a gradual penetration and replacement by chrysocolla of dacite, resting on an irregular erosion surface of Pinal schist. As mentioned before, the ore is wholly secondary and probably derived from the erosion of parts of the Inspiration orebody. Outside of chrysocolla, manganese oxide is prominent in these replacement zones. The minerals are sometimes found in kernels of concentric layers, but usually show no well defined structure. The dacite begins to show coloring at the ends of these orebodies and gradually changes to a soft crumbling material, very hygroscopic and stained black or greenish brown. The outlines of the original constituents are preserved, but the quartz generally has disappeared.

The orebodies are very irregular in outline and usually much bigger in horizontal than vertical extent. Similar in derivation are the 'copper conglomerates' of Gold gulch, where recent creek gravels cemented by limonite, chrysocolla, and copper pitch have

*Continued from *Mining and Scientific Press*, p. 449.

furnished commercial ore, though as yet only on a small scale.

Lastly, but not related to this type, I might mention two contact deposits near the Continental mine where Schultze granite approaches Devonian limestone. Strong magnetite and grossularite outcrops contain some very good copper ore (chalcocite, malachite, azurite, and chrysocolla), but the development work done thus far has not disclosed encouraging indications below. A 'white magnetic iron,' probably pyrrhotite, was reported to occur here in depth but this could not be verified.

Mineralogy of the Ore

The deposits of the district are remarkably poor in gangue minerals. Of course vein quartz occurs but only seldom in quantity or good crystals. Calcite is next in frequency, while dolomite and siderite are rare, and rhodocrosite was observed at the Cole & Goodwin mine only. Hematite, especially the micaceous variety, is frequent and in consequence also limonite. Ilmenite crystals of macroscopic size were seen in one locality. The ore minerals proper are: pyrite, chalcopyrite, bornite, enargite, chalcocite, cuprite, native copper, azurite, malachite, chrysocolla, brochantite, chalcantite, melanochalcite, copper pitch, sphalerite, goslarite, galena, cerussite, wulfenite, vanadinite, cuprodesloizite, argentite, cerargyrite, silver bromide, native silver, hübnerite, and native gold.

In the district at large are found well developed crystals of orthoclase (Carlsbad twinning), muscovite, and tourmalin, the last only in very small individuals. Magnetite and garnet (grossularite) occur in contact zones near the Continental mine. Asbestos (probably fibrous serpentine) in small quantities is found as an alteration in limestone in the Old Dominion mine, also in good fibres up to two inches in length in the Apache mountains.

Genesis of the Ores

Since granite-porphry sills participate in the primary mineralization at Miami and copper veins occur through the granite-porphry (Schultze granite) area, there can be no doubt but that the mineralization here occurred later than, and most likely in consequence of, this eruption. The not very clear relation in this district seems to establish the Schultze granite as later than the diabase, therefore the Miami-Inspiration orebody and the veins in Schultze granite must be considerably later than the diabase intrusion.

In 1902 when F. L. Ransome wrote his admirable report on this district, the Miami orebody had not been discovered and Mr. Ransome considered the Schultze granite as part of the pre-Cambrian granitic eruption. In explaining the genesis of the ores, he naturally considered the diabase as the cause of the ore deposition, being the only Mesozoic eruptive of importance, according to his then theory. Since then the age of the Schultze granite has been established beyond a doubt at Ray, as I am informed, and in this district porphyry dikes cutting the diabase have also been connected

with great semblance of probability with the later Schultze granite eruption.

In broadening the relations established at Miami many geologists have been inclined to attribute all the deposits of the district to this granite-porphry eruption in spite of Mr. Ransome's rather weighty arguments in favor of the diabase, the most important of which is probably the fact that even perfectly fresh diabase away from any fissure or vein contains traces of copper. My opinion is that the diabase is the source of the Old Dominion and related vein deposits, and that ore deposition continued through, or was revived by, the granite-porphry eruption. That ore deposition had come to a standstill and oxidation was in full swing at the time of the Tertiary dacite extrusion is proved by the fact that round water-worn pieces of oxidized ore are included in the lowest dacite-tuff beds with pieces of limestone, quartzite, and diabase.

In fact, that acid porphyrites are the sources of most copper deposits recently discovered has tended to create a little prejudice in favor of these acid rocks and has veiled somewhat the fact that copper deposits connected with basic rocks were the main copper producers until Butte gained supremacy. The vein deposits of the Old Dominion type follow, as I explained before, intrusive dikes of diabase that cut as well through sediments as diabase sills, and represent therefore probably the last exertion of the volcanic cataclysm that sent up these startling masses of basic lavas. The furnace had been stirring for a long time, had skimmed off the slag and collected heavy metals in the centre of disturbance. A renewed outbreak of volcanism carried them upward. Of course these diabase dikes might have been only the passive channels for later mineralizers, as for instance the Schultze granite, and vapors and solutions derived from this source might have followed only the mechanical lanes opened by these diabase dikes, but I personally think not.

My main reason for considering the diabase the active mineralizer is the micaceous hematite, so surprisingly plentiful in the Globe district. Naturally the diabase is a magma rich in iron, and Mr. Ransome gives for normal diabase from Globe 8.50% FeO and 2.09% Fe₂O₃, but locally, and especially in the vicinity of the vein zones, diabase will occur where the percentage of iron must be considerably higher, as hematite replaces the normal biotite, and perhaps also magnetite replaces part of the augite. Veinlets of solid micaceous hematite cut through the solid diabase away from the prominent veins, and where dikes or sills of diabase have penetrated the limestone huge masses of hematite, mostly in the micaceous form, make their appearance. Some of the altered vein dikes, especially where diabase is the country rock, are now practically only white kaolinized material with stringers and individuals of micaceous hematite. The hematite is apparently a primary mineral and not a product of oxidation; and since it occurs as well in the diabase at large as in the veins, a close relation between this eruptive

and the ore deposition is established. Many authorities, especially in Europe, consider hematite rather typical for ore deposits connected with basic eruptives, and even if this should not be accepted universally, the Old Dominion seems to offer a good example for this theory. The lack of this mineral in the undoubtedly acid porphyry deposits of Miami and vicinity, and its prominence in the diabase veins affords a good criterion in adjudging the mineralization of veins in this district to either one period or the other. The veins of the Pinal schist area, for instance, would go with the diabase veins on account of their hematite gangue; a probability still more pronounced from their similarity in strike and dip with some of the undoubted diabase veins. More doubtful is the case of the zinc and lead veins, but still I consider them rather with the basic than the acidic group, because in the first place most of them have the same northeast-southwest strike as the Old Dominion, and some, especially those with chalcopyrite in addition to sphalerite and galena, have shown hematite occasionally, even if this mineral usually is lacking where lead or zinc gains the ascendancy. But perhaps some of the veins, especially the extremely rich ones of the Old Dominion, have benefited by both periods of ore deposition even if this should never be supported by undeniable evidence.

Order of Deposition

The hematite was apparently the first metallic mineral to be deposited. After that followed the sulphides. The deposition of hematite started apparently as a magmatic segregation, but continued into aqueous or pneumatolytic deposition. Sometimes sulphides will prevail almost to the exclusion of hematite, but the latter gains prominence again, either horizontally or vertically, in the same vein and usually even in the same ore-shoot.

The sulphide orebodies have two distinct bases: pyrite on one extreme; and a combination of primary bornite-chalcopyrite-pyrite, with perhaps even primary chalcocite, on the other. Both types blend, occasionally, but are developed in their extremes without transition even in one single vein (the Old Dominion) in different ore-shoots. Prominent chalcocitization is characteristic for the ores of pyritic base, while it appears somewhat lacking in the rich sulphides. Why this should be the case is hard to explain, since the theory that chalcopyrite might break up into chalcocite and pyrite has been discouraged time and again in spite of the surprising reversability of sequence in formation of copper minerals that gain in scope as their interdependence is investigated more thoroughly.

In this connection I might mention the fact that kernels of chalcopyrite were found in entirely oxidized ore along the Carrie vein less than 50 ft. from the surface; and even the lowest depth attained on this vein, about 800 ft. below, has failed to disclose any sulphides. In fact, I do not remember ever having seen any pyrite, chalcopyrite, or bornite whatever from the

Carrie-Buckeye mine, except in this one locality.

Another peculiar occurrence is that of the west orebody on the 13th level of the Old Dominion. Here is a thoroughly oxidized orebody not far from the old surface, but now buried under perhaps 800 ft. of later and overthrust rock (conglomerates, dacite, and Madera diorite). The same orebody has been opened on the 16th level, 300 ft. vertically below, and about 500 ft. on the dip. On the 16th level the ore is fully oxidized, but on the 13th chalcocite occurs in the same hand specimens with chrysocolla, malachite, melanochalcite, and cuprite, and sometimes also limonite. Fig. 9 illustrates the occurrence.

FIG. 9. HAND SPECIMEN FROM THIRTEENTH LEVEL, WEST, OLD DOMINION MINE. LIME SHALE STAINED BY CHRYSOCOILLA, CONTAINING AREAS OF IMPURE CHALCOOCITE WITH STRINGERS OF HARD CHRYSOCOILLA CONTAINING MALACHITE AND AUGS OF QUARTZ OR CALCITE.

While this looks at a first glance like a re-development of chalcocite from oxidized ores, the fact probably is that chalcocite is the oldest of the minerals represented here and changes along fissures often concealed to melanochalcite and cuprite. The cuprite in turn is converted to malachite from the centre outward, while the surrounding chrysocolla is a later immigration and not a change *in situ*, this latter infiltration sometimes depositing malachite which also surrounds small vugs of quartz, or more rarely calcite crystals.

Another rather rare occurrence is that of flakes of native silver on chalcocite, as seen in the east orebody on the 9th level of the Old Dominion. Sometimes small sheets of native copper accompany the silver.

Zinc has been found only in one single place in the Old Dominion mine, that is, in the central orebody on the 14th level. It is found in a zone of intimate interaction of diabase with Cambrian limestone along the vein. The sphalerite here is of a light yellowish green color and traversed by veinlets of pyrite, therefore apparently the older sulphide, but the occurrence is so isolated that it hardly justifies general conclusions as to the sequence of metals.

Ore-Shoots

There is no law governing the occurrence of ore-shoots that I have been able to establish. One fact

stands out clearly, though, that when Carboniferous or Devonian limestone forms the hanging wall, the intrusive vein-dikes are liable to branch off the main fissure and pervade these limestones as dikes and sills, causing locally great and rich accumulations of ore. While we have had these orebodies only in the oxidized zone, the similarity of Bisbee shows that nothing prevents their recurrence in the sulphide horizon, provided we shall ever find limestone below the reach of oxidation.

The quartzites and the Cambrian limestone are less productive of ore outside of the veins proper, or at least only for a short distance, where they have been intensely fractured by the fault movements, but where they occur as detached blocks in the faults proper, or included between very closely spaced parallel faults, they contain some of the very choicest ore. In the upper limestones it is therefore more the deflecting of intrusive dikes and chemical exchange that produces bonanzas, while in the other rocks the bonanzas are caused by a mechanical shattering. But both occurrences are localized, and why they should have happened in one part of the vein, and fail in another otherwise apparently similar one, has defied my observation.

The joining of veins sometimes explains the occurrence of ore-shoots, as for instance the central orebody of the Old Dominion, where a vein which is probably the combination of the Buffalo and the No. 3 veins, joins the Old Dominion from the foot-wall, but in other cases such junctures have proved very discouraging. Generally it seems as if the combination of a flat vein with a steep one is more productive than the joining of the two steep veins. But there is one feature that might ultimately prove of great importance for the district. As Ransome mentioned already, the whole district is dissected by normal faults of different dip, tending to drop down triangular blocks between converging faults.

FIG. 10.

Such a system of faulting must necessarily produce strong lateral pressure. Therefore these faults will close again soon, except where resistant blocks of ground prevent this closing. The same is the case with the flat dipping veins, so numerous in the district, only that the closing pressure here acts vertically rather than horizontally.

Wherever masses of sediments have been included in the single veins or between the converging veins they have kept open channels for mineralization; and being fissured if large, or crushed by pressure where small, they have provided conditions for bonanza ore. Where two veins belonging to the same fault-block join, the ore is as a rule disappointing. This occurs frequently

enough to suggest that it will prove a rule ultimately. Of this there is a good example at the Buffalo mine.

As can be seen by comparing Fig. 11 and 12, the Buffalo is only a repetition of the same conditions that prevail at the Old Dominion vein, though on a much smaller scale. The plasticity of the diabase allowed the closing even of such a gash-vein as the Buffalo, where diabase forms both walls.

While many observations indicate that ore deposition must have been rather rapid in diabase-sediment contact zones, and far advanced before lateral pressure closed the feeding channels, there is surprisingly little

FIG. 11.

FIG. 12.

contact metamorphism, and the only true contact deposits that I have seen in the district point to the Shultze granite as their origin. These are the garnet-epidote-magnetite zones, with copper ore, near the Continental mine.

Contact Phenomena

In approaching diabase dikes a recrystallization of limestone can sometimes be noticed, and in one place on the 16th level west of the Old Dominion I have found limestone that appears to be impregnated with heavy silicates, but so small that only microscopical work could prove the occurrence. But there are frequently contact phenomena connected with the diabase intrusions that suggest an action akin to fusion, for instance, at the contact of diabase with Cambrian limestone where the limestone has changed to a transparent chert with turbid green to black inclusions and grades into aphanitic diabase of smooth surface, greasy to the touch. Layers of iron oxide have been formed rarely in the limestone also, which while non-magnetic now, probably were magnetic originally. These layers of iron alternate with others of quartz and cherty limestone.

At diabase-quartzite, and especially diabase-conglomerate or coarse sandstone contacts, round quartz grains or pebbles will be found imbedded in a diabase matrix; and this will grade into normal conglomerate with diabase magma in the interstices, or quartzite with nests of greenish minerals, perhaps chlorite. At a diabase-Ruin granite contact in the Continental mine, the large orthoclase crystals of the granite were found surrounded by diabase magma. All these occurrences are so closely intergrown that hand specimens will show both rocks in one piece.

In concluding this chapter I might point out how closely ore deposition in the limestone areas parallels the genesis of the Bisbee ores, as sketched by myself* in so far as not the solubility of certain limestone beds, but the intrusive dikes and sills gave an impetus to ore deposition which ultimately spread to the limestone also, especially where this has been pervaded by iron minerals, in this case micaceous hematite, or more rarely magnetite, pseudomorphs after which are found occasionally. These iron oxides I consider exudations of the intrusive magma.

While the Miami-Inspiration type of ore deposit has its proved tonnage, that is steadily but not largely increased by operations, it is not possible to compute the tonnage of the vein deposits in advance. The Old Dominion, though, has ore reserves that will last for several years, and in its east orebody it has a deposit that, with chalcopryrite-bornite and perhaps chalcocite as primary ores on the present deepest level, promises to continue to considerably greater depth. The west orebody is still in oxidized ore, and, while vicissitudes are bound to occur in orebodies of that type, a parallel to the very similar central orebody promises large

and rich sulphide masses for the contemplated deepening of the mine. The central orebody is in lean pyrite on the 16th level as mentioned before, after having been the only support and later on the mainstay of the mine for years, and furnishing wonderful chalcocite ore both as to quantity and quality until considerably below the 14th level.

That this pyrite horizon is the last of the orebody, I do not believe. In the first place, the bornite-chalcopryrite ore of the east orebody proves the existence of high-grade primary sulphides along the vein, and even if the rich limestone orebodies of the central and west orebody should have drained the lower parts of the vein of a part of their copper contents, a recurrence of high-grade sulphides in depth should remain a possibility, especially as a flat north-dipping vein should join the main Old Dominion vein a few hundred feet below the 16th level in these parts from the hanging wall. Besides this, all the observations confirming the primary nature of pyrite in veins cannot shake the fact that pyrite is secondary also, as shown by the sequence of (1) limonite in peat, (2) marcasite in lignite, (3) pyrite in coal. What reducing agents have accomplished in one place they also can do in others. I suspect, therefore, that the Old Dominion might help to eliminate the present belief that lean pyrite constitutes the absolute lowest limit of workable copper deposits, beyond which no recovery of copper is possible.

Outside of their main vein the Old Dominion has many other veins in its large territory, but partly or not prospected at all outside of their rich surface orebodies, and others that are being prospected in depth right now. Some of the more recent work indicates great possibilities for the very great number of veins in the district generally, that are lying idle at present. While there may not be a second Old Dominion awaiting enterprise and capital, the district is bound to flourish for a long time to come and see many a new mine rise to success.

In the course of this paper I have referred frequently to F. L. Ransome's report on the Globe district.* This has been written more than ten years ago, and while recent development has forced me to disagree with it in several minor instances, I cannot but admire how painstakingly and thoroughly Mr. Ransome worked out, in the short time allotted, a district as complicated as this one, and provided a basis for future research.

Mining Methods

Outside of the 'raise and sub-level' method of stoping developed at the Miami mine, which is a matter of record in recent magazine literature, there is very little extraordinary in the way of mining in this district. I might mention the adaptation of an inclined 'cut-and-fill' method for rather wide stopes in the Old Dominion mine, where the roof is good and the grade of ore uniform enough to eliminate hand sorting. The

**Mining and Scientific Press*, February 4, 1911, p. 203.

*U. S. Geol. Surv., Prof. Paper 12.

method is used both with open and square-set stopes. In the former I have seen stopes up to 40 ft. wide worked that way, while with the latter a width of six sets (30 ft.) was a maximum.

The stopes are worked with rising inclined face, and the ore slides automatically in the chutes over a floor of planks on top of the fill. (See Fig. 13.) The chute-

FIG. 13. SQUARE-SET STOPE AND CUT AND FILL STOPE.

raises are cribbed, and a few rounds of cribbing are placed above the plank floor to allow some of the ore to accumulate on this inclined floor, partly to protect the planks from wear and partly to give the men a better footing. After finishing a cut, these rounds of cribbing are removed, the ore run down the chutes, the raises cribbed up, the planks removed, and filling run in.

Fluorite in Smelting

By HERBERT LANG

Fluorite, a comparatively rare veinstuff in the mines of America, although abundant in those of some parts of Europe, possesses considerable interest in its metallurgical aspects, from the peculiarities of its action in smelting. It is unique in that, while a saturated substance in itself, it yet assists other and comparatively infusible matters to liquefy at a heat far below their melting points alone. In particular the native sulphates, such as those of lime and baryta (gypsum and barite or heavy spar) are enabled to melt by an addition of a comparatively small amount of fluorspar, forming a homogeneous slag having a rather low fusing point. Hence its application in some forms of lead smelting in reverberatories. It has been claimed by some, but mainly on hypothetical grounds, that the well known decomposition of fluorite by silica in the presence of steam takes place in the blast-furnace. In this case the fluoride of silicon should be evolved, while the silicate of lime would remain in the slag. From this point of view fluorspar would consti-

tute an ideal flux for silicious ores in lead and copper smelting. There is no doubt as to its effective decomposition by silica under any circumstances in the blast-furnace, but it would appear not to behave quite so favorably in ordinary practice, inasmuch as the silicon compound has probably not been detected in the gases. Furthermore, as the decomposition of the gaseous fluoride takes place in the presence of steam, which is an invariable concomitant of furnace educts, the probability seems to be that while that substance would most likely be formed, it would speedily be broken up, even before issuing from the furnace, leaving a residue of silica, which would descend again to the zone of activity below, there to become combined with the bases. The value, then, of the fluorite would depend wholly upon its calcium constituent and not, as several metallurgists have taught, in part upon the fluorine. The matter, however, is obscure; and the attention of experimenters might profitably be directed to an inquiry as to the precise part played by the volatile constituent.

As a fluxing agent fluorite is most closely comparable with limestone (calcite). The pure mineral contains 51.3% calcium, corresponding to 71.8% lime, while calcite of an equally pure quality has 56% lime. The difference, therefore, is material in this respect. In reverberatory smelting, where the action of the fluorine in determining the volatilization of silica would probably not be masked by the interference of the vapor of water, fluorite would doubtless be preferred as a flux, since one part of it should by theory saturate or expel a much larger proportion of silica than calcite could. The equivalent amount satisfied by one part of fluorite is 0.726 parts of silica, while one part of calcite satisfied 0.60 silica, assuming, which is practically always the case, that the bisilicate of lime, CaSiO_3 , is formed.

Fluorite is employed in various minor arts, especially in the preparation of castings, where it is held to be of special value as provocative of ready fusion, and as tending to purify in a certain measure the iron. It is likewise used in the manufacture of cements, in glass and enamels, in electrolytic lead and antimony refining, in the production of aluminum and in the manufacture of hydrofluoric acid, a substance of increasing use in the arts. No important deposits of fluorite have as yet been discovered in California, or at least none of sufficient purity to found an industry upon, but a more strict inquiry may reveal such. The principal localities thus far reported in this state are in Inyo county, where several slightly prospected locations are found. To the south in Arizona is the somewhat noted Castle Dome deposit, where the fluorite was found in connection with lead ores of exceptional purity, worked some years ago, and chiefly smelted at Melrose in Alameda county, in this state.

The market for fluorite is but small. Messrs. Levensaler & Spier, mineral brokers of San Francisco, report that the requirements would be met by two or three carloads per month, which may be 500 or 600 tons per year. This is supplied from the east.

The Buck Zinc Prospect Near Boracho, Texas

By J. A. UDDEN

*In the hills about 12 miles north of Boracho, in Culberson county, there is a zinc prospect known as the Buck mine. It is in a deep arroyo draining into a tributary of Coyote creek. The country rock consists of limestone of the Delaware Mountain formation. Work on the prospect has been desultory, by different people, and at different times. Ore was once packed out on burros, and shipped to Kansas City. A half carload of this ore was left near the Boracho station. A grab sample of this ore yielded 34% zinc. This ore came from two open cuts, sunk at the point where the first discovery was made on the east side of the arroyo.

THE BUCK CREEK ZINC PROSPECT. 1, OPEN CUT; 2, OPEN CUT;
3, SLOPE; 4, TUNNEL.

The largest of these cuts, 1 in the figure, is some 20 by 15 by 10 ft. in size, and is about 25 ft. above the bed of the arroyo. The other cut, 2, is about 20 yards to the northeast, and lower down. The country rock is a coarse-grained limestone, showing altered and mineralized streaks and cavities and a few small irregular veins, an inch or two in thickness, extending in different directions. Some of the veins are filled with calcite, some with smithsonite of fine and compact texture, and some with ferruginous material. Sphalerite of dark brown color was noted in some of the orebodies of irregular form, and greenish yellow sphalerite appears in streaky impregnations in the limestone. The whole has the appearance of a part of a cavernous system in a limestone partly filled by mineralizing solutions, this filling having later in part been dissolved away and to some extent oxidized by the leaching and weathering

effects of groundwater. A half dozen picked samples of the size of walnuts, from the walls of each of these two open cuts, give the following averages of zinc:

| | Zinc, per cent. | Silver, per cent. |
|------------------|--------------------|----------------------|
| Open cut 1 | 26.0 | None |
| Open cut 2 | 26.5 | None |

A piece of the limestone forming the country rock, taken a few feet from open cut No. 2, gave 2% of zinc.

A hundred yards to the northeast from these cuts, a slope, 3, about 40 ft. deep has been sunk on a vertical vein and about 15 ft. above this a short tunnel, 4, has been driven on the same vein. This vein is from 1½ to 3 ft. wide, bears about north 20° west, is filled with stalactitic calcite, laminated vertically, showing characteristic rippled surfaces of drip-stone and, in places, a transverse fibrous structure. In some places the filling is incomplete, leaving thin, open vertical fissures. The walls of the vein are straight, showing hardly any erosion or etching. The vein extends some distance above the tunnel. Samples taken across the vein in these workings gave the following assays:

| | Zinc, per cent. | Silver, per cent. |
|----------------|--------------------|----------------------|
| Slope 3 | 0.5 | None |
| Tunnel 4 | 1.0 | None |

A half mile southeast from these workings, two shafts have been sunk, about 80 yards apart. One of these is some 40 ft. deep, the other (to the northeast) 25 ft. These expose, in part, some limestone, some talus-like debris, containing weathered blocks and smaller fragments of limestone, and some sandstone and indurated white and purple clay and silt of Cretaceous age. An elongated patch of brown sandstone of Cretaceous age runs northwest immediately to the west of these shafts, and two other small elongated remnants of the basal sands of the Cretaceous are to be seen in a straight line between this patch and the two open cuts first described. Picked samples from the dumps of the two shafts contained no zinc.

Evidently the Delaware limestone has been traversed by an irregular series of cavernous openings, having a trend approximately parallel to that of the calcite vein. Owing to these openings, Cretaceous deposits found lodgment in some channels having the same trend, laid bare on the shore of the Cretaceous sea in the limestone. Present erosion has cut below the general level of the Cretaceous base, leaving only a few remnants lodged in the deepest depressions of the older rock. Mineralization of the ground must have taken place before the removal of the upper formation.

Evidently a successful exploration of this prospect will require much underground work to locate orebodies in old seams, joints, porous layers, and cavernous openings, filled by the agency of the mineralizing solutions. The pockets already found may be merely some small off-shoots from a much greater system of ore beds in filled caverns, or they may have been the

*Published by permission of Wm. B. Phillips, director of the Bureau of Economic Geology and Technology, University of Texas, Austin.

main deposit. The size of the stalagmite vein and the depressions in the lower formation containing Cretaceous sandstone, suggest the existence of an extensive system of old cavernous openings. The conditions are kin to those existing in the Shafter silver mine, though much less appears on the surface of a cavern system, than was the case at Shafter.

This prospect is on a range of hills separated from the Delaware range proper by a valley draining to the east into Coyote creek. Between this valley and the Texas & Pacific railroad, which roughly parallels the valley at a distance to the south of from eight to fourteen miles, is an anticline whose axis trends a little north of west and south of east. This anticline forms the range of hills mentioned. The prospect is north of the axis of the anticline, and on its west end, which has a higher elevation than the east end. Deep ascending mineralizing currents would naturally collect near the highest point of such a structure, and this is another reason for considering further prospecting here warranted by the natural conditions.

Rock Drilling in Lake Superior Iron Mines

By P. B. McDONALD

The general standard of rock drilling practice in the iron mines of Michigan and Minnesota is noticeably higher than five years ago. The conditions which have brought this about have been principally the lowered prices for iron ores and the coöperation of mine superintendents with representatives of rock drill manufacturers for the purpose of improving the mechanism of the drills. Efforts have also been made to improve the personal efficiency of the miners under the general principles of scientific management, but these attempts have not accomplished much; the older Cornish miners do not take readily to such innovations as standardizing plans for placing holes, record keeping, etc., and the more ignorant immigrant labor refuses to understand these processes. Incidentally it is likely that some of the smoldering resentment so apparent in the copper country strike has been due to the antagonism of old style miners to the too officious advances of scientific management under the cover of paternalism; the mine managers point out that no strike occurred in the copper country for fifty years, but the fact is overlooked that during most of that time immigrant labor, such as Finns, Poles, and Austrians, was very much in the minority and the Cornish-American miner was dominant under conditions suitable to his own ideas of mining and living.

The present status of the rock drill in the Lake Superior iron mines is much different from a few years ago when nearly all drilling was by the two-man, mounted, reciprocating machine. The stope drill is now used for practically all the raise work requiring a power drill. The cost of raising has been generally reduced to less than half the former cost. It is probable that the stope drill has worked greater economies

than any other type. On account of the mass-like shape of the large iron ore deposits, raising is an important part of many of the mining methods in vogue.

The one-man, mounted, reciprocating drill for driving and stopping (over which there was so much controversy in the copper country) has had a number of sales in the iron region, and was an efficient drill for the 'medium soft' grades of ore. It was repeatedly demonstrated that one man could accomplish the same (or greater) drilling results with this drill as previously had required two men with the old type, heavy drill. However, a new development has taken place in this line in the iron region. Unlike the tough copper country rock, the majority of the iron ore is medium soft or soft, some of the latter varieties on the Mesabi range having been drilled with hand augers for years. It has been found that a small, automatically rotated, 'plug' drill, changed so as also to be used as a power auger, is possible; that is, such a machine will work as an auger in soft ground but when a hard seam is struck it changes to a hammer drill. This new style of drill promises to be a decided success, and is expected ultimately almost to replace the one-man piston drill in the iron mines.

The general use of smaller and lighter drills in driving and sinking is resulting in a trend to the European practice of shorter holes, better placed, and a shorter cut; it is found that with cuts of 4 or 5 ft. progress can be made faster than was formerly possible with 6-ft. cuts; the light drills permit greater flexibility in pointing the holes, and can be quickly moved back out of the way for blasting, thus encouraging more frequent blasting.

For drilling the unusually hard ores and for the hard rock sometimes accompanying the iron ores, such as jaspilite and quartzite, the two-man, reciprocating drill will be retained. Another type of drill which has been successful in the hard rock (more especially true in the copper country) is the Leyner drill. This can perhaps be called a hybrid type because it is a hammer drill and at the same time is mounted on bar or tripod: the water principle of washing out rock chippings is, of course, an important feature.

In sinking, a radical change has come about. In place of the two-man, piston drill on tripod or bar, little 'plug' drills are now used. Three-quarters of the shaft sinking in the iron region is now done by automatically rotated plug drills or 'hand sinkers,' and records are being made in speed of sinking.

On the Gogebic range, the Newport Mining Co. recently sunk an 11 by 18 shaft in quartzite 33 ft. in one week, with Jackhammers and the concrete lining was put in at equal speed. Contrary to first expectations these little hand sinkers can put down deep holes when necessary. Their principal advantages lie in their one-man principle, enabling twice the number of drills to be used in a shaft, and in the ease with which they can be removed for blasting.

Depth of water in the Suez Canal is now 33 feet.

Meeting of the Canadian Mining Institute

The sixteenth annual convention of the Canadian Mining Institute was held at the Ritz-Carlton hotel, Montreal, March 4, 5, and 6, with a large attendance of members. A. E. Barlow of Montreal, the president, in his opening address referred to the steady growth and progress of the Institute, which had attained a membership of 1029, of whom 113 had been added during the year. There were now eight branches, including the Rocky Mountain and Ottawa branches recently organized. He dealt at some length with the question of the development of Canada's iron resources, urging the exploration of the Archean rocks of the hinterland, which gave promise of holding large iron deposits, and advocated the granting of a bounty on iron ore.

Mineral Production for 1913

The preliminary report on the mineral production of Canada during 1913, by John McLeish, chief of the division of mineral resources and statistics of the Department of Mines, was presented. The total value of the output was \$144,031,047, as compared with \$135,048,296 in 1912, an increase of 6.65%. The metallic production was valued at \$66,127,821, and the non-metallic at \$77,903,226. The leading items in the metallic list were as follows: copper, 76,975,832 lb., value \$11,753,440; gold, 784,525 oz., \$16,216,131; pig iron, 1,128,967 tons, \$16,540,012; lead, 37,662,703 lb., \$1,754,705; nickel, 49,676,772 lb., \$14,903,032; silver, 31,750,618 oz., \$18,984,012. There was an increased production of all the metals except copper and silver, which showed slight decreases, the most important increase being in gold with 28%. Among non-metallic products increases are shown in all the important items except clays and lime, the largest being in natural gas with 41% in value. The cement output showed an increase of 21% in quantity. Coal was produced to the amount of 15,115,089 tons, of the value of \$36,250,311, as compared with 14,512,829 tons, valued at \$36,019,044, in 1912. The record of production by provinces showed that Ontario stood at the head of the list with a value of \$58,697,602, or 40.75% of the total; British Columbia came second with a value of \$28,529,081, or 19.81%; then followed Nova Scotia with \$19,305,545, or 13.4%; Alberta with \$13,844,622, or 9.6%, and Quebec with \$13,303,649, or 9.24%. In the above comparisons, no account is taken of the large iron smelting and steel making industries of Nova Scotia, as the pig iron used there is entirely from imported ore.

Reports were also presented by Theodore C. Denis, superintendent of mines for Quebec, and from Thomas W. Gibson, deputy minister of Ontario, showing the mineral production of those provinces for 1913. The Ontario report placed the value of the mineral production at \$52,999,957, of which \$37,508,955 was metallic and \$15,491,002 non-metallic, the total exceed-

ing the previous year's production by 9.6%. The production of gold was 220,837 oz., of which more than 94% came from the Porcupine mines. The output of silver was 29,681,975 oz., showing a slight decrease. The report points out that the high water mark in silver production was apparently reached in 1911, when the yield was 31,507,791 oz. The output of nickel had increased in value nearly 11%, and copper 16%. The production of pig iron was 648,899 tons, worth \$8,719,892, an increase of 10% in quantity. The conclusion is drawn that the producing capacity of the iron mines of the province has not kept pace with the expansion of the blast-furnace industry, as of the 1,228,269 tons of ore smelted in Ontario, only 132,708 tons was of domestic origin, the remainder being imported from the United States.

The list of nominations for officers was presented and George G. S. Lindsey, of Toronto, declared elected president by acclamation. Mr. Lindsey was for some years president and general manager of the Crow's Nest Pass Coal Co. and is now president of the North Alberta Coal Company.

Papers were read at the afternoon sitting on mining and milling at Cobalt, by St. George Campbell and Fraser D. Reid, both of Cobalt, and by George A. Guess, of Toronto, on pyritic smelting. E. D. Peters, of Dorchester, Massachusetts, gave an address on the production of heat in metallurgical furnaces, dealing principally with the reverberatory type and detailing the experiments which had resulted in the production of the present furnaces, 112 ft. in length, in which the ore was melted almost immediately after it had been thrown into the furnace and the slag drawn off without much loss of heat. The furnace was charged with 15 tons of quartz once in 45 minutes, and the heat of the furnace at the fire bridge was 1500° Centigrade.

Evening Lectures

In the evening there were two lectures illustrated with moving pictures. Austin King, chief inspector of mines for the Frick Coal & Coke Co., dealt with 'Safety in Coal Mines,' and H. W. DuBois, of Philadelphia, treated of 'Hydraulic Mining.'

On the morning of March 5 the members paid a visit to the tunnel which is being constructed by the Canadian Northern railway underneath Mount Royal. They were conducted by S. P. Brown, chief engineer of the work, and J. Austen Bancroft of McGill University. At the afternoon sitting Mr. Brown read a paper on 'Methods of Excavation in the Mount Royal Tunnel.'

On March 6 a number of papers were presented and addresses delivered. H. M. Payne, of New York, spoke on 'Efficiency Engineering Applied to Mining, Quarries, and Industrial Plants.' W. McAlpine Johnson, of

Hartford, Connecticut, described an electric furnace which he had produced for the treatment of complex zinc ores on a commercial basis. This furnace is claimed to produce more spelter or zinc by the use of less power than has hitherto been found necessary abroad, despite the fact that the Canadian ores are not of as high grade as those of Norway and Sweden. W. R. Ingalls, who has been experimenting for the Canadian Department of Mines with the view of making zinc smelting a profitable undertaking, congratulated Mr. Johnson on the success of his experiments.

A. Stansfield, of Montreal, gave a résumé of recent metallurgical experiments covering the most important advances in practice during the last 14 years. Howard W. DuBois, of Philadelphia, gave a history of the use of high carbon steel plates for sluice-way linings in hydraulic mining, which had overcome the expense of heavy wear and increased the output by 25%. A discussion took place on the present status of the Canadian iron industry, and a resolution was moved by Eugene Coste, and seconded by George G. S. Lindsey, directing the attention of the Government to the fact that the iron industry was greatly handicapped because extensive deposits of high-grade ore, such as were found in the United States, Newfoundland, and Cuba, had not been discovered in Canada, though it was believed that they existed. The Government was therefore urged to take such means through the proper channels, either by a geological survey or a special committee of experts, as would determine the extent and value of Canada's iron resources. The resolution was adopted.

Studies of Smelter Fumes and Gases

*As during the previous year, the investigations conducted at the San Francisco experiment station and the field work controlled from there have centred around the problems of copper and lead smelting, with especial reference to the reduction of the deleterious gases and fumes emitted by smelting furnaces, and the recovery of the valuable constituents, now wasted, of these fumes. Considerable time has been spent in attempts to find new uses and to encourage the extension of present uses of sulphur, arsenic, bismuth, selenium, and tellurium, which are found in such amounts in these wastes that if any large proportion of the whole were collected in commercial form the supply would exceed the present demand. During the year the laboratory work has been largely devoted to the quantitative study of the fundamental chemical reactions taking place in roasting and blast-furnaces, in the converter, and in other standard smelting equipment.

A large part of current operating practice is based on empirical generalizations that have gradually been developed in the art itself. Although practice must, of course, always be the court of final resort as re-

gards the merits of a given procedure, still there are many fundamental chemical problems on which more definite and accurate quantitative data are badly needed, and which can not be advantageously studied in industrial furnaces. These are receiving especial attention in the laboratory. At the same time the attempt is being made to render the field investigations and the work in co-operation with industrial plants throughout the country serve as a medium for carrying the theoretical conclusions and suggestions from the laboratory to a point where they may be readily interpreted into practical improvements and method of closer control by those in charge of smelters. A significant and encouraging fact is the cordial coöperation in this work which has been extended from the industries concerned, even in those cases where the work in question dealt with bettering the condition of the workman or of the surrounding community without immediate prospect of commercial advantage to the operating company.

This coöperation has in many instances been wholly informal, consisting merely of the exchange of suggestions or of especial facilities for making certain tests. In other instances it has taken a more definite form, as in connection with the Anaconda and the Selby smelter commissions. Both the Anaconda plant in Montana and the Selby plant in California have been in litigation either with farmers' associations of the local or the federal government over alleged fume damage for many years, and much time and money had been expended in court proceedings by both sides without apparently reaching any permanent settlement of the general questions at issue. The court proceedings in both these cases have within the last two years been suspended, and by agreement the questions of fact have been referred to commissions of disinterested experts for investigation and report as to what improvements are possible and practicable and what relief may be reasonably expected. While those commissions are entirely independent of the Bureau of Mines as an organization, the director of the Bureau was asked to serve on each of them as an individual, and, with the approval of the Secretary of the Interior, is so doing. Each of these commissions has its own staff of scientific and technical investigators, but the Bureau is assisting the broader aspects of their investigations, in the attempt to make such of the results as do not involve confidential data available for the broad general study of these problems.

The work of the San Francisco station has been under the general direction of F. G. Cottrell, chief physical chemist, with a staff consisting of L. H. Duschak, chemical engineer (from Jan. 9, 1913); V. H. Welch, assistant physical chemist (furloughed Jan. 16, 1913, and since then in the employ of the Anaconda commission); W. Eaton, assistant physical chemist (resigned Sept. 6, 1912); D. R. Kellogg, assistant physical chemist (from Jan. 2, 1913); and E. H. Zeitfuchs, mechanic and laboratory assistant.

Application of the Magnetometric Survey to the Sudbury Nickel Deposits

By KIRBY THOMAS

The nickel minerals in the Sudbury, Ontario, district are almost invariably intimately associated with pyrrhotite, the magnetic iron sulphide, and likewise the pyrrhotite masses found in the nickel area, always contain more or less nickel and are generally commercially valuable as nickel ore. These nickeliferous pyrrhotite orebodies are found along the contact of the norite, an eruptive rock allied to the gabbro type, and a foot-wall of greenstone or granite, or as shoots or 'chimneys' accompanying the dike like 'offsets' from this contact. These contact orebodies are of a thickness up to 400 ft. and they often have a large areal extent and usually follow the contact on its dip presumably to great depths.

Measuring Magnetic Intensities

These pyrrhotite ore masses are distinctly magnetic though the attraction is not nearly as strong as in the case of magnetite orebodies of like magnitude. Owing to the fact that the Sudbury orebodies generally outcrop at the contact and extend downward and laterally along a sloping contact, about 30 to 45°, it is possible to measure the varying magnetic intensities, taking in to account the variations in distance from the needle with the increasing depth of the orebody and to note the 'curves' of the readings on either side of the actual contact.

The earlier operations in the district were confined to the prominent gossan outcrops, locally called 'burns,' but later it was found advisable to explore by diamond-drills, a method which has been very extensively and successfully applied in the district. However, the magnetic property of the ore was early recognized, and as long as ten years ago attempts were made to find the orebodies by using the dip needle, particularly in localities where the contact was covered by glacial drift or 'muskeg' (swamp). Owing to the fact that the gabbro dikes and masses often found in the foot-wall and other rocks associated with the ore were markedly magnetic also, and to the accidental but frequent presence of masses of magnetic iron ore in the drift overburden, these earlier attempts at exploration with the dip needle were generally unsatisfactory and often very misleading. In one instance a shaft was sunk on a 'magnetic centre' to the end of disclosing at about 50 ft. in the gravel a large boulder of magnetite. A little later, Thomas A. Edison became interested incidentally in a supply of nickel for his purposes and he undertook to show the Sudbury operators how to find the ore. A large staff of healthy college boys was sent afield to apply the great inventors' own particular ideas. Exhaustive magnetic readings were made

of selected areas on the nickel ranges. On the interpretation, or rather misinterpretation of these data some explorations by drilling were made, in one case to a depth of 1200 ft. but without any successful results. The fact seems to be in evidence that Mr. Edison's experts ignored the, even then, fairly well understood geologic features of the nickel-bearing formations and depended on the magnetic readings solely. The Edison incident further dampened the interest in magnetic explorations in the district. However, soon after this, the London directors of the Mond Nickel Co., interested by the development and success of the new science of magnetometric surveying as practised in Sweden, sent a Swedish expert with his new and precise instruments into the district and had extensive detailed surveys of the nickel areas made. It is said that on the records of these surveys, largely, if not solely, these London directors subsequently directed a campaign of drilling, sending their orders to the men in the field by cable each day. Be this as it may, the fact is that the drilling explorations of the Mond company for several years after this survey was made were admittedly disappointing and the succession of unsuccessful drilling explorations by this Company were attributed by the local wise men to the unreliability of the magnetic survey, corroborating a local judgment on the matter already founded on some experiences as noted.

The Canadian Copper Co., the other large Sudbury operating company, frankly avowed its disbelief in the efficiency of magnetic surveys in the district and the local property holders came to entirely disregard this possible aid in their limited attempts at exploration.

Comparison of Results

Two years ago, a new company making some explorations by drilling in Levaek township on the North range had a magnetometric survey made, but the contemporaneous explorations were not carried to a point to test the usefulness of these surveys. A year later, however, more complete drilling demonstrated it and revealed the possibilities of the magnetic survey, for the ore was found in the locality indicated by the survey and the meaning of the magnetic manifestations, before not well understood, was made clearer. Recently the Geological Survey of Canada took cognizance of the matter and a staff of the experts which had been engaged in making magnetic surveys of the Canadian iron deposits was sent to survey the area which included the No. 3 mine of the Canadian Copper Co. The survey was made by men who had no knowledge of the facts which had been actually demonstrated by drilling and later their deductions were compared with the known

conditions. The comparison was quite satisfactory and a discussion of this test and copies of the maps were published in a report of the Ontario Bureau of Mines. Eugene Haanel, director of the Mines Branch of the Department of Mines at Ottawa, continued the study of the question and as a result he has recommended to those inquiring that magnetometric work be done in the Sudbury district preliminary to and as an aid to testing by drilling. It is likely that henceforth there will be more attention paid to the possibilities of magnetic surveys in the district. The opportunity for its appli-

cation is very great as the total contact outcrop is more than 125 miles and not half of it has been explored at all and much of the remainder is at best only partly tested.

There is yet to be worked out the principles of interpretation of the magnetic data and the correlation of this with the geologic facts and relations. The surveys should be made under the direction of a geologist who is familiar with the district and who has the experience to enable him to competently interpret and apply all the available facts.

Accident Prevention in Mining

By EDWARD RYAN

*Accident prevention is a theme upon which one might dwell at great length, were he to endeavor to cover every industry, but as my work has to do with mines and mining, it is my purpose to speak to you for a few minutes on that branch of the work, with the hope that I may be able to leave with you some thought that will aid in this great movement, and possibly will strengthen the bond between employer and employee.

It is commonly supposed that by passing safety acts and having inspectors who visit the different mines every few months, all has been done that can be done for accident prevention. This is not so. Laws are merely educational means, and the penalties provided in the act are merely punishments for those who fail to learn their lesson. It is generally known that Nevada leads in laws looking to the prevention of accidents, and the protection of those who toil underground. We have taken 31 of the most important points of the law, the violation of which causes most of the accidents, and, under the heading 'Don't,' have pointed out to the employer and employee the frequent daily crises that must be provided for. These have been printed on cloth, and are furnished all operating mines, a copy being posted at the collar of each shaft and on each working level. This keeps constantly before the miner many things that must be avoided if accidents are to be lessened.

With these signs constantly before them, why do we have as many accidents as we do? There can be but one answer. The men are either incompetent, they wilfully violate the provisions looking to their safety, or they are compelled to forego the exercise of the caution pointed out by the signs, by reason of the requirements of those in authority. We all know that men constantly working in an atmosphere of danger become careless of their surroundings. They do many things they ought not to do, and daily violate state laws and company rules. The operators are often to blame for the hap-hazard and careless manner in which men do

their work, by reason of lack of discipline. Some mine foremen—the great majority—are competent in all other lines of their work, but sadly deficient in discipline. At times they are carrying out the wishes of those higher in authority, but as a general rule I believe that the attitude of the management as regards carelessness is reflected by the men. If the superintendent is careless and indifferent, the men in turn will treat rules and regulations lightly. If, however, the superintendent shows an earnest desire to have all rules closely observed, if he makes accident prevention one of the leading features in his department, his foremen will usually reflect that attitude, and in turn will compel the men to adhere closely to all rules and regulations looking to their safety.

Operators, if they wish to surround themselves with home loving law abiding honest citizens, cannot afford to neglect discipline. Slipshod methods beget carelessness and indifference, surely resulting in disagreeable conditions. Lack of proper discipline results in the gradual elimination of the better men, with its resulting increase of inefficiency, and accidents. Lack of discipline is entirely too prevalent in some of the mines of our state, and the cause 'Disobedience of orders' would not be so frequently written in accident reports, were more attention paid to discipline. Let the employee know that all rules and regulations looking to his safety are to be obeyed, and if he shows a disposition not to obey, for his own sake get rid of him. Thus you will protect him from himself, and the careful employee from his careless fellow worker.

Centralize responsibility as much as possible. What is everybody's business, is nobody's business. The Nevada Consolidated Copper Co. has recently inaugurated a system which I believe will go a long way toward securing the coöperation of employees in the matter of accident prevention. A monthly bulletin is issued showing the number of accidents in all departments of the work. The name of the man in direct charge is given, and the accidents on the different shifts and in each department are written directly under that of the one in direct charge. All accident reports are care-

*From an address by the State Mine Inspector, delivered at the 'Safety First' conference, Reno, Nevada, January 27, 1914.

fully scanned by the management and comment is made in favor of those who show a clean record as far as accident prevention goes. Not long ago I was in one of the pits when an accident happened to a man on one of the steam-shovels. It was an unavoidable accident, and the accident itself revealed and outlined the method of prevention. The master mechanic was one of the first on the ground, and immediately took steps to prevent a like occurrence. Before night every shovel in the pit was equipped with the means to prevent a similar accident. It was the first that had happened in this man's department, and it had been his constant aim to furnish the men with all possible protection. Compare, if you please, the earnestness with which this man did his work, with that of a foreman who outlined all the points of his method of doing a certain kind of work and showed that it was perfectly safe. A short time thereafter an accident happened in this very branch of the work, and, upon investigation, I found that the method as outlined was not in effect, and that he had deliberately deceived his superior.

In going through one of the mines I came upon a miner who had drilled a number of holes in close proximity to a number of missed ones. This was against the rule of this Commission, but the shiftboss in permitting it reflected the wishes of the foreman.

Far better would it have been for one of our large mining companies had they followed closely the law relative to the use of gates on cages and not permitted them to be discarded by one who doubtless thought them a useless feature, and thus involved the Company in a damage suit, and perhaps criminal prosecution by reason of a man having fallen from a cage to his death.

I want to ask you mine managers this question: Do you believe that you are doing your full duty by simply passing laws, and rules, and regulations? Some two years ago, in an address before the Engineers' Club of this University, on the subject of accident prevention, I pointed out that the common mandates of humanity should cause us all to get together on this important subject. Already, in this state, since the passage of the Employers' Liability Law, some of the mine managers have met and discussed accident prevention. Such meetings are bound to bring good results. One becomes the teacher of the others, and, as a result, all have a better understanding of the needs of the industry. Why not go further in these meetings, and take the miners in? Let them know they have a duty to perform in this humane work. Almost daily we see men exposing not only their own lives, but those of others. Many do not seem to know that what they are asked to do or not to do is not in compliance with the law. Shiftbosses cannot constantly watch over them, therefore, they must share responsibility in carrying out the law. I believe that a better understanding and spirit of coöperation that will go right down to the bottom of the staff and grip the very heart of the miner, can be had by placing the matter right square up to him.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Progress in Gold and Silver Ore Treatment in 1913

The Editor:

Sir—I read Mr. James' article in the *Mining and Scientific Press* and was surprised to note that he made an attempt to compare the relative efficiency of different agitating and filtering equipment, drawing his logical conclusion from a major and minor premise, when both were composed of the one datum—"cost per ton"; apparently not considering relatively the tonnage treated, location of plants, or character of ores as having any bearing upon the subject at hand. I feel sure that provided he had compared Nevada Hills agitating, diluting, and filtering costs with those of some plant operating at a distance of 45 miles from a branch line of a railroad, and treating 140 tons per day, the ore being of such a character that it required very strong solutions of lime and cyanide, his conclusions would have been more favorable to the type of equipment in use here.

E. A. JULIAN.

Fairview, Nevada, February 9.

Solution Control in Cyanidation

The Editor:

Sir—I should like to add a word or two, if I may, in connection with the correspondence which has been going on in your columns between A. W. Allen and James S. Colbath. The question of the determination of free cyanide has always been a puzzling one, and as my book on the 'Chemistry of Cyanide Solutions' has been referred to by the writers, it may be as well to state that the method given on page 25 (2nd edition) of that book gives results approximating to the true 'free cyanide' only when the solution contains but little other impurity except zinc. At one time I made a good many investigations on this subject, but as a matter of fact I find that practically every operator works out his own method of testing, and eventually discovers an end-point which he can recognize and reproduce within reasonable limits in making his daily tests. Whether this point really corresponds with 'free cyanide' as defined is a matter of no practical consequence; what it indicates is a condition of the solution which has been found empirically to be suitable for performing the work required of it. In testing a solution with silver nitrate, using every precaution as to filtering, and working with perfectly clean vessels, a faint turbidity generally appears almost from the first, and becomes more and more marked.

The operator stops when this turbidity becomes clearly noticeable to him, the point depending on individual eye-sight, and individual opinion as to what constitutes a sufficient degree of cloudiness for a finishing point.

It is possible that both Mr. Allen and Mr. Colbath may be right. A system of testing which answers satisfactorily with solutions from one ore might fail completely in other cases. At the Santa Gertrudis mill at Pachuca it was found quite impossible to determine free cyanide, and the attempt was given up; the solutions were always tested with KI indicator and AgNO_3 run in until a distinct yellow turbidity remained permanent, the figure obtained corresponding to something less than the total cyanide. This condition was easily observed and solutions adjusted to correspond with a given strength as indicated by this test. No inconvenience whatever resulted from the failure to determine the actual free cyanide.

J. E. CLENNELL.

Oakland, California, March 9.

Vocational Training and Miners

The Editor:

Sir—Your editorial of March 7, on 'Vocational Training and Miners,' will, I fear, raise a hope that is not yet warranted. You say that the University of Cincinnati has arranged with owners of large plants for a coöperative course, one set of pupils working in the shops in the morning and in the school in the afternoon, and exchanging places with another set at midday. In this way, there is no interruption of routine, and yet school and work are taught at the same time. I fear that this news is too good to be true. It is the plan that I have been trying for years to have adopted. When such work has been done the students have been taken from school to the shops for periods of not less than two weeks, thus most effectually breaking up the necessary routine work of the school and of the shop. When the children are allowed to give half of their daily time to shop work, and the other half to school work, we will have fairly started on a sane educational system. Your statement that "it is the absence of vocational training that endangers the present free rise of a working man from the ranks to leadership," is absolutely true. Members of the Virginia City School of Mines organized among themselves a prospecting and development company, secured ground, and developed a profitable mine—even in the supposed dead and sadly abused mining district of Virginia City, where it now seems that a round of holes cannot be blasted in a streak of ore except by order of anxious stock brokers who are also the directors.

You furnish abundant proof of how a man is made 'class conscious' in the disagreeable sense in the articles contributed in answer to your question, 'What is the matter with prospecting,' and 'A Rejoinder,' but the question has not been answered, except by the work of prospecting and development that has been accom-

plished by the members of the Virginia City School of Mines.

Frederick Burk, of the San Francisco Normal School, may not be able to tell you what is the matter with prospecting, but I am quite sure that he can tell you what is the matter with our educational system; and if his advice is followed, the mineral industry of our country will be greatly benefited, and in short order it will be possible to truthfully say that there is nothing the matter with prospecting.

G. McM. Ross.

Stockton, California, March 9.

[We can assure our correspondent that the plan advocated was actually put in operation at the University of Cincinnati some years ago and was found to work well. If it has been abandoned we have not learned that fact, but write subject to correction.—EDITOR.]

Mine Administration and Mine Bosses

The Editor:

Sir—Some time ago in your columns ran several articles by an old miner,* who had gone from 'Dan to Beersheba,' and at the end of his gypsy tour had only blame for the companies and unstinted praise for the miner. One other type only praises the miner so. That is the tenderfoot superintendent, the workings of whose mine consist of a shaft and one or two drifts. He will tell you how faithfully they work and how they never 'soldier.' Certainly they work, for he is on top of them all the time. Give him 10 levels and 250 men, and let him remain away from them, and see what they do.

As a matter of fact, much ore and efficiency is lost in all metal mines because the companies are niggardly in the number of shift bosses allowed. Take a shift boss who watches several levels, with the machine runners, trammers, shovelers, and timbermen, and follow him on his trip through the mine. He must see these men, but there is a likely streak going into the wall and it ought to be sampled; the men in the stope are breaking the ore too wide; the assays show that the ore in another stope has left the foot and is running in the hanging; or a rich streak has come into the drift and maybe it ought to be stripped. Meantime he must make his round and the ore must come up, and he cannot give his close attention to these important but smaller details. Eventually the mine goes on a leasing system. The ore is blocked. The lessees go on the blocks and give almost microscopic attention to its streaks, the courses of the ore, the timbering—to all the things that make money. A good shift boss can do the same, and extra shift bosses would be paid for easily out of the ore they would find. The closer to a leasing method a mine runs when on company account, the better it is run, and that ideal is approached by using a greater number

of competent underground bosses, and putting each man in charge of a block of ground not too large for him to handle it closely in all ways.

'A Miner' also tells of the gales of profanity directed at the men. I never saw that. It is not needful. I know a gold mine that lifted 90,000 tons last year from a single-compartment shaft without that. But the most interesting statement of 'A Miner' he makes again and again, namely, that there are mine bosses that make a man do "two days work." Those mines I do not know. I want to know them. I want to see one of them, and I want to make a low bow to the superintendent and his foreman. What I have seen at every mine is a new man land on the station, turn to the old hand and say, "What's a day's work on this mine?" Or translated it means, "What is the smallest amount of work that I can do and still hold my job?"

A PERPLEXED SUPERINTENDENT.

Cripple Creek, Colorado, February 10.

Milling Operations at the Eldorado Banket Mine, Rhodesia

The Editor:

Sir—The statement of milling operations at the Rhodesian Eldorado Banket mine, which appeared in your November 1 issue, is of interest, but would probably have demanded more attention if the combined recovery by amalgamation and cyanidation had not been shown to amount to something over 110%. This was evidently due to a printer's error. The metallurgical staff and the scheme of treatment should both be credited with the satisfactory results of the year's work, and I have therefore ventured on a corrected summary.

| | | |
|--------------------------------|---------------|-----------|
| Tonnage treated | 88,209 | |
| | Value of gold | |
| | content. | Per cent. |
| Original ore | \$12.93 | |
| Recovered by amalgamation..... | 9.36 | 72.52 |
| Mill tailing | 3.57 | |
| Recovered by cyanidation | 2.76 | 21.24 |
| Residue | 0.81 | |
| Total recovery | | 93.76 |

These figures are compiled from extracts from the annual report appearing in the same statement. It is also interesting to note that the actual recovery is within one per cent of the theoretical extraction; and that the total cost for cyaniding is 60c. per ton.

A. W. ALLEN.

Lonely Mine, Rhodesia, December 11, 1913.

Nitrate production in Chile during the first 10 months of 1913 was 2,551,744 short tons. The price in November was \$1.85 per 100 pounds. The Chilean government is alive to the fact that in the majority of nitrate works methods are out of date, therefore it is investigating the situation with a view to improving the mining and production of the mineral.

*'Mine Administration and Mine Bosses,' *Mining and Scientific Press*, March 1, 1913.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A correspondent wishes to know if any reader of this journal has details of a Chilean (Bryan) mill being worked as an arrastre.

Oil production of the Balakhany-Sabunchy-Ramany, and Bibi-Eibat (Baku region) districts, of 2498 acres in Russia, since 1870, total 1,382,200,000 barrels.

Potash salts exported from Germany in 1913 totaled 1,829,617 metric tons. The agreed deliveries of the potash syndicate for foreign and domestic consumption in 1914 is to be 1,166,600 tons.

For ordinary steel shafting carrying pulleys, the horse-power transmissible per 100 revolutions may be found from the following formula: $2 \times S^3$, where S equals the diameter of the shaft in inches.

The circular shaft at the Champion Reef mine, India, has been bricked to a vertical depth of 3861 ft. It is now being fitted with steel girder dividers and 92-lb. steel rails as guides. This material weighs 700 tons and cost \$52,800. Two engines have been erected for hoisting.

Trolley wires have been dispensed with in the Bunker Hill & Sullivan mine, Idaho, and Mt. Morgan, Queensland. In place of these, electric storage locomotives are to be used in the former, and horse traction in the latter. The danger of overhead wires to employees has brought about these changes.

The ore deposits of Charters Towers, Queensland, occur as shoots in numerous distinct lodes of the ordinary fissure type, a prominent feature being the tendency of the lodes to split into branches which usually unite again; but which may become several hundred feet apart before doing so. The main workings of the mines are within an area of 4000 ft. square, and are down to a vertical depth of over 2600 feet.

Blasting rock is frequently done in large quantities. At the Kelly Butte quarry, Multnomah county, Washington, the face was 80 ft. high. Holes were bored and charged with 1250 lb. of 40% Du Pont 'straight' dynamite, and 560 kegs of Du Pont 'B' blasting powder. The work was well done, and no noise was made save that of the rolling rocks grinding against one another. The rock dislodged amounted to 21,373 cubic yards.

A simple though unusual arrangement was adopted at the mill of the Silverton Mines Ltd., Silverton, B. C., for driving the two, 8 ft. by 30 in. Hardinge mills there in use. Water under pressure being available, two small

Pelton wheels were used, one for each mill. The wheel was in each case mounted on a shaft set parallel with the axis of the mill and geared direct to the latter. Regulation of the water supply permits easy and simple control of the mill.

Turbo air-compressors are being used in America for air at all pressures up to 100 lb. Large installations have recently been erected for blast-furnace work, both the steam and air ends being turbines. The Tennessee Coal, Iron & Railroad Co. has recently installed a machine of this class which is giving a volume of 55,000 cu. ft. per minute at from 18 to 22 lb. pressure. This machine may be run either through exhaust or live steam, a regulator being supplied by which it is shifted from one to the other as the exigencies of the case demand, according to W. L. Saunders, in the *Compressed Air Magazine*. The largest air-compressing plant in the world is now in service on the Rand, and the fact that this plant is being enlarged from time to time is an evidence of the success of the turbo system.

Uranium minerals have been considerably discussed by the mining world of late, on account of the radium that they contain. According to Frank L. Hess, of the U. S. Geological Survey, Colorado and Utah supplied the only ores in this country in 1913. The output was 2140 tons of dry ore, containing an equivalent of 38 tons of uranium oxide. According to the Bureau of Mines estimates, the metallic radium content of the ores was 8.79 gm., or 16.40 gm. of radium bromide, worth about \$1,055,000. The total value of the carnotite ores sold was about \$142,000, representing the uranium value only, as little was paid for the vanadium content. The increased output in 1913 was about 50% over that of the previous year. Of the output, 19.25 tons of uranium oxide, containing the equivalent of 8.3 gm. of radium bromide, was exported to Europe. The Survey has been investigating the deposits in these two states.

The efficiency of native labor is often compared with that of white labor about mines. During September of the past fiscal year, the Champion Reef mine, India, employed a total of 6716 men, of whom only 143 were Europeans, mainly overseers. During the year, 277,336 tons of 'rock' was extracted from the mine, and if there were 3686 natives underground, as given in the report for September, the output per man was 75 tons per year; and figuring on the above and below surface employees, 6716 in all, the output was 41 tons per man. In Western Australia, in 1912, the ore mined was 2,688,868 tons, and the work done was 365 tons per year per man underground, and 204 tons per man of the total employed at mines. It would seem, therefore, that the relative efficiencies were about as five to one. At the Mt. Morgan mine, Queensland, ore produced per underground employee is 1.32 tons per 8-hour shift.

MANILA, PHILIPPINE ISLANDS

GOLD OUTPUT IN 1913.—SYNDICATE, KEYSTONE, AND COLORADO MINES.—DREDGING FIELDS.—CANSURAN HYDRAULIC PLANT.—AGUSAN BASIN.—NEW PLANT FOR THE BENGUET CONSOLIDATED.—MINING EXHIBIT.—PROPOSED STOCK EXCHANGE.

The past year shows a considerable increase in the gold production over 1912. The estimated figures for the past year are over ₱1,500,000, and the output for 1914 promises to be over ₱2,000,000.

The Syndicate mine, in Masbate, has just started operations, the mill having been completed in record time for this

turned from that country, bringing back a small bottle containing ₱35 worth of coarse gold which was taken from a hole dug for water less than a cubic metre in size. The Company is employing about 150 men. By May 1, it is hoped the first clean-up will be made. The following equipment will be in operation: About 1½ miles of hydraulic steel piping, ranging from 11 to 24 in. diameter; 1½ miles of flume and ditch; 4 miles of tramway; a 200-hp. Pelton water-wheel, a 150-kw electric generator; an electric lighting plant; an air-compressor and drill; and a logging engine.

Considerable prospecting has been carried on in the Agusan river basin, and recently a prospector brought in some pyrite pebbles which gave fairly rich assays. It will be recalled that similar pyrite pebbles have been found in the bank of the Rand. A prospector who has just returned from Antique province, Panay, has brought in some good specimens of copper ore, containing metallic copper, cuprite, malachite, and some chalcopryite. The deposits lie within 14 minutes' walk of the beach, and are said to be extensive.

R. Y. Hanlon, well known in the Philippines as a competent mining engineer, has gone to the United States to purchase machinery for the rehabilitation of the Benguet Consolidated property in Benguet. It is planned to install an up-to-date plant capable of handling 80 tons of ore per day. It is hoped that the plant will be in operation before January 1, 1916. The former mill on this property was washed away in the typhoon of October 1909.

Much of the machinery for the Rizal Cement Co. is now on the ground at Matiquio, Jala Jala peninsula, Laguna de Bay. This concern is capitalized at ₱1,000,000.

The Division of Mines of the Bureau of Science is preparing a comprehensive exhibit for the second Philippine exposition. The exhibit will contain many new minerals (not new to science), maps, pictures, and a large assortment of working models. It was expected that the provincial exhibits would be found to contain many valuable mineral specimens. Unfortunately, just a week before the opening of the exposition, the entire provincial exhibit was burned out and many samples from the provinces were destroyed or misplaced during the resulting confusion.

There is a movement on foot among the more conservative Manila business men to establish a stock exchange. This, if properly controlled, can do much to help the legitimate mining companies and also to protect the public from overenthusiastic promoters. The Division of Mines of the Bureau of Science is well aware of the evils existing and the harm done to the country, but has no authority to act in an administrative capacity. The mining industry is menaced by two evils which must be remedied namely: florid prospectuses and subsidiary companies.

The political situation has improved somewhat, and it is hoped that, when the 'independence bogey' has been put to sleep, capital will again be forthcoming to grease the machinery of business which of late has become somewhat clogged.

country, about eight months. This is an all-sliming decantation plant, Hardinge ball and pebble mills being used instead of stamps and tube-mills. The Keystone company, operating two Lane mills, has sent two shipments of precipitate to Manila; but so far it has not been learned what the recovery of bullion was, although it is said to be satisfactory. The Colorado mine continues its steady progress.

In the dredging fields, the new boat on the Umirai river is about to begin operations, and from the Malaguit encouraging reports have been received. The sixth dredge in the Paracale district is about to be constructed, and the output in 1914 from this district is estimated to exceed ₱1,000,000. In the Cansuran district of Mindanao, hydraulic machinery for the Cansuran company is already being installed. Some difficulty has been experienced due to transportation troubles, but this will soon be overcome. D. M. Carman has just re-

PLATTEVILLE, WISCONSIN

BAD WEATHER INTERFERES WITH WORK.—METAL PRICES DURING FEBRUARY.—ORE PRODUCTION BY DISTRICTS.—PROSPECTING.

February was this year still further kept from making a good showing in the production of ores on account of severe winter weather, heavy snowfalls, and at times exceedingly bad roads, affording neither wagoning nor sledding for the outlying producers. The metal markets advanced at the beginning of the month, spelter being quoted on the St. Louis exchange at \$5.40, but the little gains made were not long upheld, and the close of the month saw metal back on a basis of \$5.20 per 100 pounds. Large consumers were indifferent to the requirements of their trade it seems, during the month, and spelter producers were operating on about two-thirds

capacity purposely trying to maintain prices. This course on the part of spelter manufacturers undoubtedly served to hold the price where it remained. Zinc ore was especially in good demand, the finished ore ruling steady for the month at an average of \$14 per ton for 60% grades. A top price was reached for premium grade out of the Linden district of \$43. The lower grades were not in such good demand, and The Mineral Point Zinc Co., which usually sets the pace in bidding had little competition in the field from local buyers or outside smelters. Conservatively estimated there was held in bins at the close of February 4500 tons of reserve zinc ore concentrate which will act against higher prices until this surplus is eliminated. Carbonate zinc ore producers in the northern districts could not get to track with their output at all, and as fast as roads improve pile their product alongside of track where it will be available as soon as a demand sets in, and most likely the spring break up will prevent carting for several weeks. Lead was in poor demand and shipments were exceptionally light.

Deliveries by districts for the month of February from mines to separating plants in the field, and thence to smelter were reported as follows:

| Camps. | Zinc, pounds. | Lead, pounds. | Sulphur, pounds. |
|-----------------------------|------------------|------------------|---------------------|
| Benton | 4,684,000 | 83,500 | 2,337,300 |
| Livingston | 2,620,000 | | |
| Galena | 2,366,000 | | |
| Hazel Green | 2,340,000 | | |
| Cuba | 2,104,000 | | 1,407,600 |
| Linden | 1,852,000 | 164,920 | 315,900 |
| Platteville | 1,790,000 | | |
| Shullsburg | 1,610,000 | 75,000 | |
| Harker | 892,000 | | |
| Highland | 448,000 | 61,300 | |
| Montfort | 138,000 | | |
| Mineral Point Locals | 34,000 | | |
| Mineral Point Zinc Co. | 2,300,640 | | |
| Total | 23,178,640 | 384,720 | 4,060,800 |

Regardless of weather conditions prospecting with drilling machines was prosecuted vigorously, especially in the southern districts of the field, and invariably with excellent results. One strike occurred in the Mifflin district, but the men only remained out a few days, returning on promise that better wages would be paid at the first opportunity following improvement in ore prices.

SYDNEY, NOVA SCOTIA

METAL MINING PROSPECTS.—NOVA SCOTIA STEEL & COAL CO.'S OPERATIONS.—COAL MINING AND THE ACADIA COAL COMPANY.

Metal mining in the province has been practically at a standstill. In Guysborough county it is stated that a good body of manganese ore has been discovered. It will be interesting to see whether any valuable development will be made or only a poor prospect, such as has frequently been offered from this county in the past. At Ingonish, in Victoria county, a small gold mine is being steadily opened to a productive stage. No plant has as yet been ordered, but the complete laboratory equipment keeps the concern abreast of development. This is the only gold mine operating in the island of Cape Breton.

The Nova Scotia Steel & Coal Co. has just completed the most profitable and promising year of its existence. The facts given in the annual report show that the earnings amounted to \$1,225,953, an increase of 25% over 1912. The sum of \$527,886 is carried over to credit of profit and loss account, after providing for depreciation, sinking fund, interest, and dividends. Considerable improvements have been

made in the mining plant and in the steel works. In the latter department, a new open-hearth steel furnace has been started successfully. The iron ore mines of this Company, on Bell island, Newfoundland, are extensive, and now reach the large total of 91 square miles, held under title from the crown. Some of the undersea workings are as far as three miles from the shore, and at that distance the ore is 25 ft. thick. This gives an idea of the extensive reserve of ore that this corporation holds.

Coal mining in the province appears to be falling into bad repute. Following the trouble with the finances of the Drummond mine, belonging to the Intercolonial Coal Co., the Acadia Coal Co.'s mine has ceased operations. The reason assigned is that there is no profit, at present prices and costs, in operating the mine. This statement has evoked considerable feeling in the district, and there is a disposition on the part of the workers to force the provincial government to challenge the Company's statement and take a hand in the dispute. Some time ago there was a proposal mooted, that the government should acquire some mines of its own, and if this idea was seriously given, now is the chance to carry it out. During the latter part of February there have been a number of meetings at Halifax between Mr. Evans, the general manager of the Acadia Coal Co., Charles Fergie of the adjoining Drummond mine, and C. J. Coll, a former manager of the Acadia, and it seems likely that some deal will be consummated whereby the Acadia mine will probably be operated by the Intercolonial Coal Company.

KALGOORLIE, WESTERN AUSTRALIA

WAGES AT NORSEMAN AND MEKATHARRA.—THE LANCEFIELD TO START AGAIN.—VICTORIOUS MINE.—OROYA LINKS IN 1913.—BULLFINCH RESERVES.—NEW PLANT FOR CHAFFERS.—FINGALL AND ASSOCIATED OPTIONS.

The Norseman wages agreement having expired, a fresh agreement, to remain in force until December 10, 1916, has been duly entered into and signed. The basis of pay is 8 cents per shift higher than the Kalgoorlie schedule, and this was accepted by the Chamber of Mines. The Mararoa is the only mine at Norseman on the dividend list, and as the bottom of the mine is unprofitable, it will soon cease to be on this list. The Meekatharra miners' union recently submitted a new schedule to the Chamber of Mines, but as it contained advances from 18c. to \$1.08 per shift, it was returned as frivolous, and the men are still working under the old schedule which is 20c. per shift above Kalgoorlie rates. Only three mines are paying dividends at Meekatharra and they are all owned and worked by working miners. There are three capitalized companies at work, but none of these has so far returned anything to shareholders.

The Kalgoorlie & Boulder Firewood Co., one of the principal creditors, has bought the Lancefield mine for \$27,800, this being the only tender submitted for the property. This mine has produced \$4,140,000 from 540,000 tons, or \$7.66 per ton, but has never paid its way, and when it closed down the company was \$200,000 in debt. The ore reserves in the mine were estimated by Bewick, Moreing & Co. at 250,000 tons assaying \$8 per ton; but this grade was not considered profitable. There is a 40-stamp mill, and a sulphide plant consisting of 8 Krupp ball-mills, 6 Edwards furnaces, filter-presses, etc., on the mine, and all are included in the sale. The mine is now in charge of J. Dunstan, at one time metallurgist at the Associated, and subsequently inspector of state batteries. Mr. Dunstan expects to make a profit of selecting the ore, and so raising the grade slightly above the general average of the mine.

The Associated Northern company's Victorious mine at Ora Banda is proving disappointing on No. 6 level. The first ore-

shoot met with is only 40 ft. long and assays \$14.75 per ton. A blank of 77 ft. intervenes, and then a second shoot 30 ft. long assaying \$19.20 was opened. The drift has been continued another 36 ft. in barren country. Owing to the creep in the upper levels, little if any oxidized ore is available, and there is talk of stopping the treatment plant. It is not quite decided if developments in the sulphide zone warrant the installation of a sulphide plant. The Company's old Iron Duke lease at Kalgoorlie is also nearly worked out.

During 1913 the Oroya Links company treated 139,130 tons, yielding \$748,700 and a profit of \$130,600, besides placing \$6000 to bullion reserve and equipping and overhauling the Croesus shaft at a cost of \$21,800. The directors have just declared a dividend of 5%, amounting to \$71,800. As expenditure on capital account is now complete, a minimum profit of \$15,000 monthly is anticipated in the future. The Croesus shaft is down 939 ft., and cut the lode at a depth of 932 ft., and followed it in the shaft for 7 ft. The first 3 ft. assayed \$6.50 and the last 4 ft. \$4.80 per ton.

On December 31, 1912, the ore reserves of the Bullfinch Proprietary mine were estimated at 177,300 short tons, of a recoverable value of \$10.36 per ton. Since then 52,677 tons has been treated, returning \$690,100, equivalent to \$13.10 or \$2.74 per ton over the general average of the mine's reserves. The extremely rich ore on which the mine was sold has been drawn on to some extent, and as it cuts out a little below 100 ft., it cannot last much longer. To give some idea of how rich this ore may be judged from the fact that 1776 tons treated returned \$430,000. It will be interesting to know what new estimates A. Hay, the present manager of the mine, will give. The north and south series of lodes have been opened during the year, but are not up to the average estimated a year ago.

The directors of Chaffers have decided to install a new sulphide plant with a capacity of 7000 tons per month, and the management is already busy dismantling the old plant. The development done since John Morgan's report, dated May 1912, has opened no reserves except the ore broken in opening the lodes. Most of the work since done has merely shown that the west branch of the No. 3 lode carries assay values of \$26 per ton for a length of 180 ft., and that No. 4 lode assays \$8 per ton over 326 ft. for the full width of the drift. The west branch of No. 3 lode is 427 ft. from the shaft, and No. 4 lode 529 ft. west, and as this drift is quite isolated, the ventilation is bad, and there is no level above or below to connect with. Mr. Morgan estimated the ore reserves as 75,000 tons returning \$6.60 per ton, but that quantity will soon be eaten up by a plant treating 7000 tons per month.

The Great Fingall company has acquired a six months working option on the Big Bell mine, 18 miles west of Cue. Two big lodes, one quartz and the other schist, the latter 60 ft. wide, run through this property, and, according to careful sampling, average \$6 per ton. Prior to Hope Nicolson, the manager, securing the option, the mine had been thoroughly sampled by the Great Boulder Proprietary people, but was turned down by Richard Hamilton as unsuitable.

The directors of the Associated appear so convinced that the calc-schist intrusion has 'knocked the bottom' out of the mine that they have acquired an option on the North Thompson mine at Porcupine, Canada, in addition to the interest in the Keeley mine at Cobalt. During last year the whole attention of the management of the Associated has been concentrated on the upper levels of the mine above the calc-schist, but nothing striking has been discovered, so the company is emigrating. Up to date, quite a lot of money earned by mining companies in Australia has been lost by their emigrating to other parts of the world, but the Associated may be luckier than the Great Fingall, Boulder Perseverance, Lake View Consols, and many others, who all had disastrous experiences.

The Ivanhoe mine produced gold worth \$158,000 from the treatment of 20,240 tons of ore in January. This was divided into 9170 tons of sand, 9020 tons of slime, and 2050 tons of concentrate. The 100-stamp mill worked 29.25 days. The profit was \$48,500. The main shaft is down 2953 ft. in country, assaying traces. The rock-crusher station has been burned, and the mine will be shut down for three weeks. At the Associated, a turbo-generator set has been working for about four years. Connection has recently been made with the power lines of the Kalgoorlie Power & Lighting Corporation, and the forty odd motors in the plant are being driven from this source. If satisfactory, the turbo will probably be stopped. A creep in the Bullfinch has affected the mine from the surface to the 210-ft. level.

The gold output of the state in December was valued at \$2,260,000, and a total of \$26,784,000 for 1913, against \$26,208,000 in 1912. Since 1886 the gold output is valued at \$547,500,000. Principal yields in December were as follows, all being low on account of the Christmas and New Year holidays:

| Mine. | Tons. | Value. | Profit. | Dividend. |
|--------------------------|---------|-----------|---------|-----------|
| Associated | 8,343 | \$ 48,000 | \$ 370 | |
| Associated Northern: | | | | |
| Iron Duke | *735 | 14,000 | 3,800 | |
| Victorious | 6,515 | 31,200 | 100 | |
| Bullfinch | 6,330 | 67,200 | 40,300 | |
| Golden Horse-Shoe | 19,749 | 97,000 | 33,500 | |
| Gt. Boulder Proprietary | *15,194 | 230,000 | 128,000 | 328,100 |
| Gt. Boulder Perseverance | 14,088 | 77,000 | 2,400 | |
| Great Fingall | 4,379 | 49,000 | 19,500 | |
| Ivanhoe | 19,380 | 172,800 | 62,400 | |
| Kalgurli | 9,720 | 97,000 | 43,200 | |

NEW YORK

BRITISH COLUMBIA COPPER CO.'S AFFAIRS.—COBALT NEWS.—BRADEN OUTPUT.—MASS CONSOLIDATED, ST. MARY'S MINERAL LAND, AND OSCOLA CONSOLIDATED REPORTS.—GEOLOGICAL WORK IN CHINA, AND FINANCES.

As mentioned in previous letters, the British Columbia Copper Co. is being reorganized. On March 17 the Company announced that 315,101 shares of the stock had been deposited out of a total outstanding of 591,709. Also a good deal was deposited with the trust company. As a result of these deposits, the plan for the organization of a new concern, to be known as the Canadian Copper Co., Ltd., is declared operative. During the year ended December 31, 1913, the Company's revenue was \$1,904,693, against \$2,491,288 in 1912. The profit was \$111,856, but in writing off \$465,736, and paying dividends of \$88,756, there was a deficit of \$442,596. The present surplus is \$523,140. F. R. Weeks, in charge of development at the Gardner and Vancouver properties at Copper Mountain, states that reserves are about 1,000,000 tons of average grade ore. The Hedley Gold Mining Co., also operating in British Columbia, has declared a dividend of 30c. per share. In 1913 net profits were \$405,254, and dividends \$360,000. The present surplus is \$272,095. For the three months ended January 21, 1914, the Granby Consolidated made a profit of \$167,861.

In a winze below the 225-ft. level of the Cobalt Lake mine, the '2B' vein is 2½ to 3 in. wide, containing 5000 oz. per ton and good milling ore on either side for several feet. The mill may be increased to 175 tons per day capacity. Ex-

traction in 1913 was 81.3%. Preliminary work for the draining of the lake is in progress. It is probable that the Van Cutsem interests in the Cobalt Townsite, Cobalt Lake, City of Cobalt, Townsite Extension, and Cobalt Reduction companies will be consolidated with a capital of \$7,500,000. The Nipissing main shaft is 900 ft. deep, the lowest point in the district. Silver shipped in February was 697,506 oz. The Company has declared quarterly dividends of 5% each. La Rose has also paid a 2½% distribution. The last annual report of the Casey Cobalt Mining Co. shows that reserves of silver blocked out in the mine, in stopes and on dumps, are 1,438,500 oz. Ore treated was 7444 tons, yielding 256,697 oz., with 84.1% recovery. The tailing assayed 6.5 oz. per ton. The total expenditure was \$150,862, equal to 22.7c. per ounce. A dividend of 24c. per share was paid. During the 11 months ended September 30, 1913, the Cobalt Townsite Silver Mining Co. of Canada, Ltd., treated 34,125 tons of ore averaging 21.12 oz. silver per ton. Shipments of concentrate, slime, ore, and bullion amounted to 1,987,922 oz., worth \$1,206,594. The cost was 23.44c. per ounce. Net earnings were \$629,623, as against \$512,082 in 1912. Dividends of \$1.44 per share were paid. Ore reserves contain 2,140,560 oz. silver. The lower-grade ore is of greater extent than was expected, and a half interest in the Northern Customs mill was purchased.

During February the Braden mills treated 79,296 tons, averaging 2.08% copper. The recovery was 68.63%. This figure is somewhat lower than in January, when an extraction of 72.70% was made on ore averaging 2.15%. The copper production was 2,362,000 lb. The production would have been greater had it not been for a shut-down in the power-plant which delayed operation several days. This was due to one of the electric generators being out of commission.

Like all other copper mines in Michigan, the Mass Consolidated Mining Co. suffered through the miners' strike in 1913. At present, conditions are approaching normal, and the Mass mine is being restarted. Development has been done at several levels at 'B' and 'C' shafts. A considerable tonnage is developed on the Evergreen and Ogima lodes, according to the superintendent, E. W. Walker. Results were as follows:

| | |
|---|-----------|
| 'Rock' stamped, tons | 78,250 |
| Refined copper output, pounds | 1,213,545 |
| Average price received, cents per pound | 15.6 |
| Total revenue | \$189,557 |
| Mine and milling expenses | 157,591 |
| Total expenses | 217,564 |
| Deficit | 28,006 |
| Strike expenses | 10,274 |

The St. Mary's Mineral Land Co. owns over 107,146 acres of land in the copper districts of Michigan, and holds shares in a number of mining companies, the Champion being the most important. The lands held are not sold outright, but the Company helps in the formation of new companies and in development of properties. The income during 1913 was \$846,739, including cash on hand from 1912, \$150,370; dividends from the Champion, \$450,000; notes collected, \$215,000; interest, \$10,170; and wood and timber, \$14,661. Expenses were \$621,835, including dividends of \$480,000; Winona assessment, \$56,778; Houghton assessment, \$37,222; taxes, \$25,255; and salaries, \$14,275. Cash on hand at the end of 1913 was \$224,903. The assets consist of 93,033 acres of unsold land, 14,113 acres of mineral rights, 269,016 shares in 18 mines, \$34,276 notes receivable, and \$224,903 cash. There are no liabilities.

The Osceola Consolidated Mining Co. is one of the more important copper mines in Michigan, and the report for 1913 shows the following:

| | |
|---------------------------------|------------|
| 'Rock' stamped, tons | 735,044 |
| Copper production, pounds | 11,325,010 |

| | |
|--|-------------|
| Copper sold, pounds | 10,958,926 |
| Revenue from copper | \$1,753,626 |
| Total revenue | 1,774,810 |
| Net profits | 381,967 |
| Dividends, deficiency taken from surplus | 721,125 |
| Surplus | 1,549,300 |
| Cost per pound of copper, cents | 12.30 |

Operations were hampered by snowstorms, scarcity of trammers, and the strike. Only one-man machines are now used in the mines. The new electric pumps, costing \$33,541, are saving \$500 per month. No. 5 stamp has been remodeled.

It has just been made public that M. L. Fuller and F. G. Clapp are making the geological surveys in China upon which the Standard Oil Co. is to undertake development under terms of the agreement noted in the editorial columns last week and in the news columns earlier. Messrs. Fuller and Clapp are graduates of the Massachusetts Institute of Technology who, after some years on the United States Geological Survey, resigned to go into general consulting work. With offices in Boston and Pittsburgh, they have been brought into intimate contact with the oil industry, and their employment indicates the care with which the Standard is going into its new venture.

In its issue of February 7, the *North China Herald* states that China has better security to show now than last year, or even during the past 10 years. There is also the added security of the salt revenue, and remote provinces have promptly sent in their collections to the foreign banks, even when the central government had little control over them. These collections are increasing. The most noteworthy change in the monetary position is that the Chinese have brought out their money and are using it for business. While the total stock of silver is being reduced day after day, the total with the foreign banks following the same course, the stock with the native banks has been rapidly increasing. Not for years have the native banks had so much *sycee* in their control as at present, in spite of the fact that credit has been rapidly expanding during this period. The holdings in Shanghai by banks and others consist of £5,350,000 in *sycee* or currency, and £170,000 in bars, an increase of £67,000.

TORONTO, CANADA

BOUNTY ON IRON ORES URGED.

The Ontario Associated Boards of Trade, together with other interests closely identified with mining in northern Ontario, have adopted a resolution for presentation to the Dominion Government asking that a bounty be placed on all iron mined and shipped from mines in Canada. They also ask that a commission be appointed by the Canadian Government for investigating conditions and report to the Government on the same. Notwithstanding the immense resources of iron ore in Canada, and particularly in northern Ontario, the production of iron ore for 1913 was valued at only \$424,072. This is largely due to the fact that only a very small percentage of Canadian ores are available for blast-furnaces until they have been concentrated or beneficiated in some manner. The cost of this beneficiation and the heavy expenditures necessary for plant and equipment in opening up iron mines of this character, has placed them at a disadvantage in competition with American ores, and it is believed that if a bounty sufficient to offset this difference were to be paid by the government, that it would greatly stimulate iron mining throughout Canada, and particularly in Ontario, and that the local ores could supply the greater part of the requirements of Canadian furnaces. In 1913, while iron ore to the value of only \$424,072 was mined, the value of the pig iron produced from Ontario furnaces was \$8,719,892.

General Mining News

ALASKA

KNIK

(Special Correspondence.)—Doheny and Thompson, the new owners of the Gold Bullion mine, are freighting in 100 tons of mining equipment, including a cyanide plant. The Alaska Gold Quartz Mining Co. is driving an adit during the winter. All prospectors coming in from the Matanuska-Nelchina placer camp speak well of the new district, and they have taken in 100 tons of supplies from Knik, the nearest outfitting

KNIK, ALASKA.

point, for summer use. Several thawing plants are on the ground. The Burke party has a hole down 55 ft. in muck on Crooked Creek bench. The last 5 ft. panned black sand and broken quartz.

Knik, February 9.

ARIZONA

The itinerary for the U. S. Bureau of Mines rescue car No. 3 in this state is as follows, during March and April: March 7 to 12, Clarkdale; 13 to 18, Wickenburg; 19 to 24, Ray; 25 to 31, Tucson; April 1 to 6, Bisbee; 7 to 12, Clifton; 13 to 18, Morenci; 19 to 24, Globe; and 24 to 30, Miami.

COCHISE COUNTY

Following up its 'Safety First' work, the Copper Queen company requires every man starting work on its property to have a physical examination and prove his fitness for the class of labor at which he will be employed.

GILA COUNTY

(Special Correspondence.)—The Miami mine produced 102,416 tons of ore in February. The mill is treating 3500 tons per day at present. Development covered 2610 ft. A Socorro fan will be installed underground. Of the seven main structures for the Inspiration company's plant, the American Bridge Co. will finish the shop and warehouse first. Steel work for the crushing plant and storage-bin is nearly complete, and the main shafts' head-frames are well under way. One hundred cars of steel for the concentrating plant are expected to arrive soon. A trestle, to span Geneva gulch and enter the mill above the ore-bins, will be 1800 ft. long and 120 ft. above the foundations at the highest point. McArthur Bros. have finished steam-shovel work at the site of the 5,000,000-gal. reservoir. Work at the smelter is progressing rapidly.

Miami, March 14.

MOHAVE COUNTY

(Special Correspondence.)—A week's trip through this county by a Los Angeles mining man has shown him that there is more activity on many properties than for several months past. The Arizona Venture Corporation is installing a gasoline hoist and machine-drills at its mine 60 miles south-east of Kingman.

Los Angeles, California, March 9.

CALIFORNIA

AMADOR COUNTY

According to C. H. Dunton, collector of minerals for the exposition to be held at San Francisco in 1915, this county will be well represented. He visited every Mother Lode mine from Plymouth to the Zeila at Jackson, and promises of help were made.

ELDORADO COUNTY

There is said to be a good deal of activity in the Union mining district, three miles north of Eldorado. The Woodland Mining Co., working the Orum mine, has recently been incorporated with a capital of \$250,000. The hoist is being overhauled and a 10-stamp mill is being built. They will be driven by 40 and 20-hp. gasoline engines, respectively.

INYO COUNTY

No. 1 well, drilled in Death valley for the Pacific Coast Borax Co. by D. H. Wallace, is down 1000 ft. This was done in 17 days. The entire well shows a series of hard salt strata, each from 1 to 20 ft. thick, alternating with similar strata of clay more or less saline. To 250 ft. the salt is sodium chloride, but from this point to the bottom, principally sodium sulphate. No significant potash results are reported. No. 2 well is being drilled about six miles north of No. 1.

The Standard Consolidated Mining Co. operates a gold mine at Bodie, and its report covers the year ended February 23, 1914. The superintendent, C. E. Grunsky, Jr., gives the following information: Work was mainly devoted to treating the balance of the tailing in the ponds, prospecting in the mine, and economizing generally. The tailing held out to September 1913, and 10,151 tons was treated, worth \$5.43 per ton. Five lessees worked at the beginning of the year; but save one, they ceased mining before their terms were up. The last lease was taken over by the Company and was the only one which produced good ore to the Company's advantage. The mine produced 6342 tons of ore to September, averaging \$13.08 per ton. Stoping was done on 15 different veins at a cost of \$10.50 per ton. The total bullion from all sources was \$132,944, with 96.3% recovery. Costs per ton of mine ore were \$16.97, and per ton of pond tailing \$2.79, totaling \$135,595. Milling operations were stopped, but exploration for ore is being continued. A dividend amounting to \$44,598 was paid, making \$5,274,408 to date. The total output to date is \$16,457,839. Cash on hand is \$20,448, and bonds \$25,284. Excess of assets over liabilities is \$79,715. The present condition of the Company's property is not encouraging.

MARIPOSA COUNTY

(Special Correspondence.)—D. E. Upton is in Mariposa on his way to Mt. Pinocke, on the south fork of Merced river, a few miles southeast of the Hite Cove mine. He will examine the Little Wonder property of 14 quartz claims owned by H. Kiburg and F. H. Catheywood. The mine is said to be opening well. E. P. Kellogg and W. H. Reed, of Tonopah, Nevada, have gone to the old Dingley mine, while G. L. Kennedy, formerly of Tonopah, and William Melburne, have been making an examination for some time. David F. Degan, of Kansas City, Missouri, and George Meesey, of Los Angeles, passed through Mariposa on the way to Jerseydale to examine the Comet mine. Mr. Degan is one of the owners of this property. It is equipped with a modern 10-stamp mill, concentrators, and assay office. It is expected extensive development work will be done in the near future. Chas. A. Schlage-tee, landlord of the Mariposa hotel, visited his mine, the Golden Gate, in company with an engineer who took a number of samples. These showed high gold content, probably assaying over \$30 per ton. A deal is said to be pending. L. C. Worthington and Thomas Smith have been examining the

shut down for many years, a vertical shaft was sunk 455 ft. and cross-cutting done at 200 and 375 ft. A further 200 ft. of driving will be necessary at 375 ft. to cut the rich shoot above. Several buildings are on the property, and water and electric power is obtainable nearby. In a few months the mine should be able to supply 75 tons of ore per day.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Idaho Springs district produced 118 cars of ore in February, against 102 cars in that month of last year. The increase in metal value was \$10,000. Shipments from the Donaldson mine average 50 tons of \$70 gold-silver smelting ore per week. The vein was cut 1900 ft. in the Rockford adit. J. F. Wernecke of the Empire Zinc Co. of Denver is making ready to construct an electrolytic smelter in this city, which will be placed in the vicinity of the New-house tunnel. Electric machinery, costing \$5000, has been started at the War Dance mine, operated by the Rockford M. L. company.

Idaho Springs, March 3.

EAGLE COUNTY

It is just over a year since the rush to the Eagle district took place. Since May 1913 the Lady Belle has been shipping ore regularly. The North Dakota has sent out some ore, and the Best Chance has its bins full. The Lady Belle No. 4 and Grand View have cut ore. Besides the mines just mentioned, there are the South Dakota, Eagle King group, Selmas, Little Mary, Little Mary No. 1, Chester group, Rainbow, Contact, Kingston, Clinton's, Montana, Irma, and Inez, all being prospected.

The Iron Mask mill, near Red Cliff, has been working continuously for five years, treating the zinc-lead-gold-silver ore from the Iron Mask mine. The tonnage has varied from 80 to 120 per day.

FREMONT COUNTY

Miners in the Oak Creek cañon, near Canon City, claim to have opened a rich vein 1000 ft. long and from 2 to 8 ft. wide, containing gold, silver, lead, tungsten, uranium, and vanadium. For three miles around, the country has been staked. Snow is interfering with prospecting just now.

GILPIN COUNTY

The property of the Buckley Mining Co., next to the Gunnell mine at Central City, has been taken over by a number of prominent Salt Lake and Utah men and the Company reorganized. R. P. Morris is president. The mine has already produced \$200,000. The main shaft is down 630 ft. and is well equipped. The mine is drained by the Newhouse tunnel. Ore reserves are about 200,000 tons, worth \$14.05 per ton, mostly gold.

LAKE COUNTY (LEADVILLE)

Work at the Yak tunnel will result in changing the direction of the main bore from its present course. The Moyer drainage lateral is being altered for the main track to go through it, and so avoid the heavy ground just above the cut-off to the Cord winze. This winze is producing a large tonnage of sulphide ores, and the stopes are of great size. The Walker adit, in South Evans gulch, is in about 225 ft. in hard rock. The Consolidated Virginus Mining Co. is working the Virginus through the old Puzzler adit. W. E. Bowden and S. J. Sullivan are owners of the property. Development includes the opening of a body of ore abandoned by the old owners. Lessees at the Star of the West have opened a small vein assaying up to 2000 oz. silver and 40% lead.

TELLER COUNTY (CRIPPLE CREEK)

There are 20 lessees at the Golden Cycle mine extracting profitable ore.

During January, Stratton's Independence produced 5683

tons of ore averaging \$5.68 per ton. Low-grade mine and dump ore treated, 10,900 tons, with a mill profit of \$5500, a mine loss of \$3000. Development has been stopped to reduce expenses. Philip H. Argall, general manager, expects to open a good shoot of ore at 400 ft. shortly.

IDAHO

CUSTER COUNTY

(Special Correspondence.)—Two new discoveries have been made this winter on the upper middle fork of the Salmon river. A shipment of one ton of ore to the smelter returned \$83. A six-ton mill-run is being made on another which assays about \$100 in gold per ton.

Stanley, February 25.

MISSOURI

Missouri has only two smelters at present which are handling zinc concentrate, one in St. Louis, St. Louis county, and the other at Nevada, Vernon county, their retorts in 1913 totaling 2672.

JASPER COUNTY

Miners' phthisis is apparently prevalent in the district mines, and work is being done by the Jasper County Anti-Tuberculosis Society to help minimize the complaint.

MONTANA

SILVERBOW COUNTY

The Butte & Superior flotation plant treated 30,900 tons of ore in February, yielding 10,422,047 lb. of zinc from concentrate averaging 51.75% zinc, with 89.81% recovery. Rich ore is being mined on the 900-ft. level. The Butte-Duluth leaching plant treated 3200 tons with 89% extraction. The copper output was 65,000 lb. of electrolytic and 40,000 lb. of precipitate. Machinery for the new 1000-ton capacity in 8 hours crushing plant is on the property. The purchase of the mine by the American Metal Co. has fallen through, according to the president of the Butte-Duluth, A. B. Wolvin. At 1500 ft. in the East Butte there is 4 to 5 ft. of 5 to 6% copper ore and 10 oz. silver per ton. In February the Butte-Ballaklava shipped about 2400 tons of ore. Seventy feet of fair ore is being mined at 1200 ft. There is 30 in. of 20% copper and 25 oz. silver ore at 2400 ft. in the Tuolumne mine. February earnings were \$6500.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The directors of the Diamondfield Black Butte Reorganized Mining Co. will probably erect a mill in the near future. The Butte-Goldfield company will also install mining machinery within the next month or two.

Goldfield, March 15.

NYE COUNTY

It is announced that the Morning Glory claim, application for patent to which was adverse on report of a Forest Ranger, has been clear listed for patent, the objections having been withdrawn. The case attracted some attention and was discussed in the *Mining and Scientific Press*, June 28 and August 2, 1913.

STOREY COUNTY

The Mexican Gold & Silver Mining Co. is being sued by A. F. Coffin, of San Francisco, for \$75,000 for alleged libel. Similar suits have been filed by several other share brokers of that city.

WHITE PINE COUNTY

During February there were only 18 disabling accidents at the mines and works controlled by the Nevada Consolidated Co., according to *Safety First*, its monthly bulletin. This is a reduction of 15 from preceding months.

NEW MEXICO**GRANT COUNTY**

United States Bureau of Mines rescue car No. 3 will be at the Chino copper mine at Santa Rita from May 1 to 5.

UTAH**BEAVER COUNTY**

A cyanide plant of 15-ton daily capacity is being operated by A. B. Blainey and others, lessees at the Sheep Rock mine. It is probable that a Kelly filter-press will be installed.

JUAB COUNTY

In unprospected ground of the Eagle & Blue Bell, at Eureka, a drift on the 1550-ft. level has cut 24 in. of silver-lead-gold ore worth about \$20 per ton. The mine is producing 100 tons of ore per day.

SALT LAKE COUNTY

After trying a number of fume-control devices, the American Smelting & Refining Co.'s Murray plant is now working full blast with no smoke issuing from its smelter stack.

WASHINGTON**FERRY COUNTY**

(Special Correspondence.)—The following ore shipments were made from Republic mines to smelters in January: Republic Mines Corporation, 8077; Ben Hur Leasing Co., 5177; Quilp, 401; Knob Hill, 2906; Rathfon Reduction Works, 44; and Black Tail, 185 tons. The San Poil mill treated about 3000 tons, of which 594 tons, included in the above, came from the Knob Hill mine. A meeting of the creditors of the Republic Mines Corporation was held at Spokane on March 7. There are several liens on the claims and taxes to be paid. On the 200-ft. level, the Ben Hur Leasing Co. is developing the vein north and south of the shaft. At the south, \$17 gold has been opened. On the 300-ft. level, the north drift is being extended beyond where the vein has produced over 100 tons of ore per day for the past six months. A stope is being raised to 200 ft., and contains 2000 tons of \$13 ore. The 400-ft. level north drift has been driven 350 ft. on the vein, and good shipping ore has recently been opened. At 600 ft., the south drift is in \$1 to \$9.20 ore. The Company employs 55 men, has good machinery, is in good financial condition, and has a lease until October 12, 1915. Five feet of ore worth \$31 per ton has been cut 150 ft. below the lower adit level of the Knob Hill.

Republic, February 27.

WYOMING**CROOK COUNTY**

There has been a rush to the new gold district near Eothen, in this county, 23 miles west of Belle Fourche, in South Dakota, near the boundary of the two states. Sixty claims have been staked. In a shaft sunk by Brownfield, Atwood, and Pearson, rich ore has been opened. There are good roads from Belle Fourche to the district.

NATRONA COUNTY

The Standard Oil Co. has started refining oil at its large plant at Casper. The oil supply comes from the Midwest's pipe-line to the Salt Creek field.

CANADA**BRITISH COLUMBIA**

A carload of molybdenite ore has been shipped from a mine at Sheep Creek, near Nelson, owned by Ross and Bennett. This is about the first of such ore sent from the province. Good progress is being made with the Hedley Gold Mining Co.'s power dam on the Similkameen river. Forty men are employed. Receipts from the Trail smelter from 1407 tons of ore and 100 tons of concentrate, from the Le Roi No. 2 mine were \$28,666 in January. The profit was \$8260. From 2241

tons of ore the Van Roi produced 210 tons of zinc concentrate worth \$18,329.

ONTARIO

The Wettlaufer Mines Co. has suspended work on the South Lorrain property. The last ore shipment was 14 tons of 204 oz., and 79 tons of about 1200 oz. silver ore. The annual report of the Cobalt Lake Mining Co. shows that the reserves contain 4,796,940 oz. of silver, an increase of 2,661,900 oz. over 1912 on account of draining Cobalt lake. The 1913 output was 973,676 oz. Dividends were \$315,000.

On April 1 the Porcupine Crown company will pay its first dividend, amounting to \$60,000. Two shifts are sinking the main shaft of the Dome mine from 425 to 575 ft. Cold weather has delayed erection of new machinery at the mill. The Dome Lake shaft is down 275 ft. During January the Hollinger mill treated 12,813 tons of ore worth \$13.57 per ton, with 96.33% extraction. Costs were \$5.012 per ton, and the profit \$101,663. Diamond-drilling covered over 1000 ft. with good results.

On the 75-ft. level of the Teck-Hughes, at Swastika, four inches of rich gold-bearing ore is being driven on. The McIntyre mine is to be connected and worked at 600 ft. by a cross-cut from the Pearl Lake mine. Ore worth \$8 has recently been opened.

KOREA

The Seoul Mining Co., operating the Suan concession, in Whang Hai province, reports the following results for February:

| | |
|--------------------------|----------|
| Stamps working | 40 |
| Time, days | 26 1/2 |
| Ore crushed, tons | 5453 |
| Total recovery | \$42,027 |
| Operating expenses | 21,500 |
| Net earnings | 20,527 |

The Oriental Consolidated Mining Co. produced bullion worth \$141,225 from 24,705 tons in January. There was a shortage of water at Tabowie and Kuk San Dong. The Taracol tube-mill plant was stopped permanently on January 14, as it was not economical and was a technical failure. The leaching method is again being used, and results are satisfactory. The net saving, compared with regrinding and agitation, should be considerable. The February clean-up was worth \$149,000.

MEXICO**MEXICO**

The El Oro mill treated 22,420 tons of ore and 15,680 tons of tailing in January, yielding \$258,860. Including \$5300 profit from the railway, the net return was \$126,090. The rate of exchange on which these figures were calculated is ₧2.70 Mexican for \$1 United States currency.

The Esperanza Mining Co.'s profit for the last quarter in 1913 was \$216,000. Additions to the mill are practically complete, and in December 26,720 tons of ore and tailing was treated. The San Carlos vein is narrower and broken above No. 9 level. No. 12 and 13 levels are lower grade than No. 10 and 11 levels. On No. 13 the ore is 5 ft. wide. Reserves, estimated by the consulting engineers, amount to 114,000 metric tons of dry ore with a profit of \$420,000, and a profit of \$240,000 in old tailing.

PUEBLA

(Special Correspondence.)—Owing to the continued activity of the 'constitutionalists' in the Aire Libre district, the Teziutlan Copper Co. has shut down its mine and smelter. T. Skewes Saunders, the superintendent, has gone to England. The rebels have been robbing mails, blowing up bridges, holding up trains and robbing passengers, dynamiting freight trains, looting towns, mines, ranches, etc., and demanding large sums of money from mines and other industries.

Aire Libre, February 9.

Personal

H. C. CARR is on his way to Brazil.

BULKLEY WELLS is in San Francisco.

CHARLES BUTTERS left for London last Wednesday.

FREDERICK BRADSHAW was in San Francisco this week.

E. H. LESLIE and THOMAS T. READ were in Pittsburgh last week.

D. C. JACKLING and SEELEY W. MUDD have been to the new gold rush near Ray, Arizona.

KIRBY THOMAS has removed his office from 42 Broadway to 43 Exchange place, New York City.

MILTON C. DUNHAM has returned to West Bridgewater, Massachusetts, from Abangarez, Costa Rica.

A. E. DRUCKER has opened offices at 62 London Wall, London, where he will engage in consulting work.

HENRY KRUMB has returned to Salt Lake City from the East, where he has been on business for several months.

W. R. CALVERT, of Utah, is in Wyoming looking over the oil-fields in the interests of the U. S. Bureau of Mines.

J. P. IDINGS will lecture at Yale University March 23 to April 3, inclusive, on 'The Problem of Volcanism.'

A. R. GORDON, general manager for the New York & Honduras Rosario Mining Co. at San Juancito, Honduras, is in New York.

POPE YEATMAN sailed from the Braden mine, Chile, on February 5, and is expected to arrive in New York about April 1.

W. F. WHITE, president of the Aguacate mines, sailed from New York on February 28 for Costa Rica; he expects to remain about a month.

M. E. LOMBARDI, in charge of the field operations for the Kern Trading & Oil Co., of San Francisco, has returned from a trip through the Westside fields.

C. J. LONDON, of Philadelphia, will be in Colombia for the next four or five months; while there his address will be, care of Empressa Hanseatica, Barranquilla.

Guests present at the presentation dinner of the Mining and Metallurgical Society of America, in honor of Mr. and Mrs. H. C. HOOVER, were as follows:

Alexander, Miss
Barbour, Mr. and Mrs. Percy
Ball, Mr. and Mrs. S. H.
Bates, L. W.
Bates, L. W., Jr.
Best, W. N.

Walker, Arthur.

The U. S. Civil Service Commission announces an open competitive examination for assistant explosives engineer, on April 8, 1914, at places throughout the country, and information will be given by writing to Washington, D. C. The subjects are physics, general chemistry, mining engineering, and education and experience. The salary ranges from \$1620 to \$2100 per year.

Obituary

GEORGE WESTINGHOUSE, who died of heart disease at his New York home March 12, was one of the men we like to think of as typically American. Of German-Dutch descent, his ancestors had been in this country since before the Revolution. Educated in the public schools and Union College, then but a small institution, serving while still a boy as a volunteer in the Civil War, he early turned his attention to invention, in that following in the footsteps of his father. He was born at Central Bridge, New York, in 1846, and before he was fifteen had invented a rotary engine. His first great invention, the air brake, was made in 1869, and for the next ten years he was mainly concerned in its introduction and improvement. This led naturally in 1880 to studies and inventions in connection with automatic signaling, and that to lights, and so in 1886 into electrical work. Here his great achievement was the setting of the alternating current to work, and power generation just as naturally made him a pioneer in the steam-turbine field. He became a great manufacturer as well as inventor, and a public citizen of the sort that is a national institution. It is pleasant to record that his success was widely recognized during his lifetime, and it is to be noted that he was successful because of natural ability, unfailing industry, and because his work was useful. It was directed to increasing safety and decreasing waste, and it answered to the world's needs.

| Zinc dust, 100 kg. zinc-lined cases, 7 1/2 to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

New York, March 19.—Although copper has been down to 13.95c. per lb., it is on the upward turn, demand being strong and more business doing. There was an increase in domestic enquiry and prices went above 14 cents. Copper mining stocks are a trifle higher. Lake copper is 15c. Rio Tinto is paying a dividend of \$8.40 per share. Lead and spelter are quiet with practically no change. Tin is firm at 38.25c. In London, copper is £64 8s. 9d. to £64 18s. 9d.; lead, £19 17s. 6d.; spelter, £21 10s., and tin, £174 7s. 6d. Aluminum in February varied from 18.50 to 19 cents.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

| Date. | 1913. | 1914. | Average week ending. | 1913. | 1914. |

| June | 59.03 | | Dec. | 57.73 | |

Writing on February 26, Samuel Montagu & Co. say as follows: The undertone continues good, and prices have been well maintained. Business during the week has been unusually active, and the shipment to Bombay will be considerable. Great stringency for delivery exists in that city, and a premium of over 2 1/2% is quoted for spot silver. The stock in Bombay has risen from £50,000 to £80,000, and the offtake from 110 to 120 bars per day. An Indian currency return shows a decrease in the note issue of 20 lacs, in the holding under the denomination of silver rupees of 5 lacs, and under that of gold of 10 lacs. It is reported that a famine is beginning to be felt in the United Provinces of India, owing to a shortage of rain. The trouble, it is feared, may assume serious proportions before the monsoon breaks in June. Sir James Mes-ton, the lieutenant governor, who has opened a relief fund, stated that the deficiency of the rainfall is greater than that of 1907. Fortunately, the succession of so many years favorable to agriculture has given the populace ability to resist a certain amount of adverse circumstance. In China, trade and the government's position is bright. Holdings of silver in Shanghai total £5,520,000. A shipment of £35,000 was made from San Francisco to Hongkong.

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

Copper amounting to 30,000,000 lb. was booked for export at 14 1/4c. per pound on March 16. The American Smelting & Refining Co. supplied about 8,000,000 pounds. Exports to March 12

were 19,330 tons. The Sulitjelma company, operating an Elmore flotation plant in Norway, produced 1070 tons of copper concentrate in February. The German consumption of the red metal in January was 14,101 tons, against 14,968 tons in the same month of 1913. Of the 1914 imports, 12,323 tons was from the United States.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | 1913. | 1914. | Month. | 1913. | 1914. |
|-------------------|-------|-------|--------|-------|-------|
| Feb. 19 | 39.00 | | Mch. 5 | 39.00 | |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Month. | 1913. | 1914. | Month. | 1913. | 1914. |
|--------|-------|-------|--------|-------|-------|
| Jan. | 50.45 | 37.85 | July | 40.70 | |
| Feb. | 49.07 | 39.76 | Aug. | 41.75 | |
| Mch. | 46.95 | | Sept. | 42.45 | |
| Apr. | 49.00 | | Oct. | 40.61 | |
| May | 49.10 | | Nov. | 39.77 | |
| June | 45.10 | | Dec. | 37.57 | |

The following tin statistics for February are from L. Vogelstein & Co.'s monthly report: Shipments from Straits to London, America, and Europe, 6544; from Australia, 201; Billiton sale, 185; imports of Chinese tin into England and America, 510; imports of Bolivian tin to England, Germany, and France, 1346; total supplies of 8766 tons, against 7263 tons in February 1913. Monthly deliveries of standard tin in England were 1610; Holland, 1232; America, including Pacific, 3420; Europe, 575; and Bolivian-Chinese, 656; a total of 7493 tons. Visible supplies are as follows: in England, 4366; landing and in transit, 975; afloat from Straits, 4003; and Australia, 301; Banca spot in Holland, 1155; Billiton spot and afloat, 356; Continent spot and afloat, 1128; U. S. stocks and landing, 1554; and afloat to U. S., 4605; total visible supplies of 13,443 tons, against 13,410 tons in February 1913, and 17,170 tons in January 1914. The average price in New York was 39.885c. per pound, and in London from £173 5s. to £188 per ton.

WOLVERINE COPPER MINING CO., Kearsarge, Mich. \$1,500,000 in \$25 shares; owns \$80,000 interest in Michigan Smelting Co.; controlled by J. R. Stanton; mill on Traverse bay treated 388,500 tons during last fiscal year. Total in 1913, 4,488,000 pounds.

Book Reviews

MINE SAMPLING AND VALUING. By C. S. Herzig. With a chapter on 'Sampling Placer Deposits,' by Chester Wells Purington. P. 163. Ill., index. Published and for sale by the *Mining and Scientific Press*. Price \$2.

In writing a full and comprehensive book on this subject Mr. Herzig has made a welcome and valuable contribution to the literature of mining. The sampling and valuing of mining properties is a subject that is almost ignored by most writers, except for an occasional article upon some particular phase of the subject. Since T. A. Rickard published 'The Sampling and Estimation of Ore in a Mine,' no book adequately covering this subject has appeared, so this present volume supplies a long felt want in an important field. Mr. Rickard's book was compiled from a series of different articles and letters written by himself and other engineers, and was therefore not a systematic and complete text-book. Such a work Mr. Herzig now supplies. It is written by a practical engineer for the benefit of mining students and young engineers who are striving to gain practical experience. Most of our schools of mines give the students so little information and training in this important branch of mining that Mr. Herzig's book should appeal both to students and teachers. The experienced engineer will not fail to find many points of interest or value, for every man has certain methods of his own which are often useful to others, and Mr. Herzig's book is based largely upon his personal experience and practice. The author is a graduate of the Columbia School of Mines, and has had a vast amount of experience in many parts of the world, including the Rand, Australia, the United States, Mexico, Central America, and Siberia. He is exceptionally well qualified by training and experience to write upon the subject of mine sampling. The chapter on 'The Sampling of Placer Deposits' contains an excellent description of the most approved modern methods and practice for the valuation of alluvial deposits, written by Mr. Purington. The subject is treated in the clear and authoritative manner that is indicative of the wide experience and thorough knowledge of the writer. The chapter not only contains a fund of valuable information, but is also written in a delightfully lucid, readable style.

MANUAL OF HYDRAULIC MINING. By T. F. Van Wagenen. P. 123. Index. D. Van Nostrand Co., New York, 1913. For sale by the *Mining and Scientific Press*. Price \$1.

The fourth edition of this popular little book. The work has been revised and brought up to date by the addition of considerable new matter. Being intended for the use and guidance of the practical miner, the book is very elementary and simple. There are lessons in arithmetic and problems in elementary hydraulics which may be of assistance to those who lack a common school education. The tables and formulae are useful, but the miner must make his calculations by 'rule of thumb' methods, as there are no adequate explanations of the formulae given.

HYDRAULIC DATA. Compiled by H. D. Coale. P. 90. Ill., index. Published by the Pacific Tank & Pipe Co., Los Angeles, California, 1913.

Nearly all of the most useful tables and formulae for hydraulic work are found in this convenient little volume. Although this book is largely an advertisement of the products of the company, yet it will be of great value to all those engaged in hydraulic work of any kind. The tables for the flow of water through wood pipe, for the contents of round tanks, and for water pressures are especially complete. The book is distributed gratis to hydraulic engineers, superintendents of water works, and others.

THE OIL FIELDS OF CRAWFORD AND LAWRENCE COUNTIES. By R. S. Blatchley. State Geological Survey. (Illinois), Bull. 22, p. 422, Atlas, Urbana, 1913.

This long expected report covers the two leading counties of the Illinois oilfields and includes detailed structural maps as well as sections, drill records, and all needful data. The Illinois oilfield, while it seems now to have passed its prime, had produced to the end of 1913, 208,112,868 bbl. of oil worth approximately \$153,000,000. Situated in an open prairie country of few rock exposures, the finding of the field came as a great surprise in 1905. The maximum production, 33,143,262 bbl., was attained in 1910, but while the output has since declined, this has been more than offset by the increase in the selling price of the oil.

The State Geological Survey began work in the fields within a few months of the first discovery and has published various brief reports upon it. Mr. Blatchley's bulletin is, however, the first comprehensive study based upon close detailed work. It is welcome as affording an excellent guide for the close drilling that must be done to insure the maximum of production from the territory. It is to be regretted that the report has been so long delayed, but it is to be remembered that other and shorter bulletins were issued in ample time to aid in the actual exploration of the territory. Whether, along the deeply buried overlapping edge the Mississippian and lower Pennsylvanian formations, there are other oilfields still to be found cannot be answered with certainty though it would seem to be entirely probable. If there are any such fields Mr. Blatchley's report will be of the greatest assistance when they are found as well as in further work in southeastern Illinois.

MINE OPERATORS and others who wish a copy of the California law covering workmen's compensation can obtain it upon request addressed to the Industrial Accident Commission, 525 Market street, San Francisco.

QUEER ways to raise capital are continually coming to light. The *Wall Street Journal* recently printed an advertisement from a confiding Argentinian who wished capital for exploration and development of a gold mine in his country on the basis of retaining a 30 per cent royalty. The only evidence submitted that the mine was valuable, was the statement that chemists of the Argentinian mint had analyzed the ore and found it to contain $87\frac{1}{2}$ grains, 8 grams per 1000 kilograms, roughly \$9 per ton. It is a long venture to make on one assay.

STANDARDIZATION is the order of the day, and engineers will read with interest the suggestion of Mr. Lloyd Robey with regard to the need of standardizing screen tests and a method of accomplishing uniform results. Mr. Robey's discussion of the subject is based upon work done while superintendent of the mill and cyanide plant of the New York & Honduras Rosario Mining Company, and this, with the significant results of Mr. E. M. Hamilton's studies of cyanide at the Butters Divisadero which we also print, draws attention to the fact that Central America is more than a land of perennial revolutions; it is a region in which technological studies of moment are being conducted and mining is done by most modern methods.

MEDICAL examination of men applying for work will be required at the Copper Queen mines hereafter. This is the natural and inevitable result of the newer laws regarding compensation for accidents. If the companies must assume the direct burden of expense in all industrial accidents, they must necessarily refuse to employ men who are not physically able for the work to be performed. The reasons are as sound as those that forbid a railroad employing a man who is color-blind as switchman or locomotive engineer. It is probable that in time a certificate of physical soundness will be required at all the larger mines. About two years ago this requirement was made at a number of New Zealand mines, and, while there were minor strikes as a result, the system was adopted and is now in force. A defective has no place in a mine.

United States Steel Corporation Report and Finances

Publication of the report of the United States Steel Corporation for 1913 brings out, as usual, most interesting figures. The Corporation is our largest industrial concern, and its business is eagerly watched as an index of prosperity, just as its methods are widely copied as reflecting the best development of corporation management. In general, public opinion is not unfriendly to the Steel Corporation. It is recognized that, passing the initial injection of water into the capital, the company has been ably and conservatively managed. While manufacturing costs have increased rather than the reverse, and hence fail somewhat to

confirm the enthusiastic claims for efficiency of large units that were especially current at the time the Corporation was formed, methods of production have been improved, quality has been maintained, working conditions, while still leaving much to be desired, are distinctly better and are steadily improving, foreign trade has been greatly stimulated, and the competition of the so-called 'trust' has been fair and even generous. If prices have been maintained at an artificial level, as permitted by our tariff laws, they, at least, have not been pushed to the limit during periods of unusual demand. On the whole, we believe that the general public looks upon the United States Steel Corporation as a successful venture into big business, and wishes it well rather than the reverse.

In 1913 business opened well and heavy orders were carried over. As a result, the output of plates and finished products equaled 88 per cent of the total annual capacity of the mills. The cement production amounted to 93 per cent of capacity. Taking into account the amount of plant that must always be down for one reason or another, this is an excellent showing, only dimmed by the heavy curtailment of the last quarter of the year. The size of the business conducted is well known and need not be restated. It is sufficient to say that 28,837,451 tons of iron ore was mined, that the blast-furnace production amounted to 14,080,730 tons, and that a total of 12,374,838 tons of iron and steel products were sold. The figures are large, but not strikingly different from those for 1912, nor, presumably, from those that will be announced for 1914 and immediately succeeding years. There is another phase of the annual report that deserves more attention.

When the Corporation was organized, preferred and common stock was issued. Shortly thereafter, part of the preferred stock, drawing 7 per cent dividends, was exchanged for bonds paying 5 per cent. At present the Corporation has outstanding bonds and debentures amounting to \$627,097,376; preferred stock, \$360,281,100; and common stock, \$508,302,500. In addition there is \$589,542 outstanding in the stock of subsidiary companies not held by the Corporation and \$9,865,809 of purchase money certificates and similar obligations. In a broad way, all the common stock represented water when the Corporation was formed, and much of the preferred stock had represented water when the constituent companies had been organized. Since the United States Steel Corporation began operations, it has consistently put excess earnings back into the business until much of the stock that originally stood for water now stands for property and plant. In the judgment of some students there is property to cover the whole of the securities. In the meantime bonds have been maturing, and have been retired, though it is to be noted that other bonds have been issued. For example, from April 1 to December 1, bonds and mortgages aggregating \$110,158,174 were retired, but during the same period there was \$106,-

757,480 of new bonds and mortgages issued, sold, or assumed. There is now a total of \$9,388,000 in bonds subject to sale; practically the amount needed to retire the certificates issued in the course of the year in purchase for iron ore properties. Apparently the Corporation makes little headway in the matter of retiring its fixed obligations, and in that it but follows the usual custom of American corporations political and private. It is being rapidly forgotten that a bond is a note, secured usually by a mortgage. A farmer expects to pay off the mortgage on his farm, and we think him a poor financier if he does not do so. But the managers of big business corporations apparently have given up all hopes of 'paying the mortgage.' All they expect to do is to issue new bonds in place of old ones, and, if the market be not propitious, they substitute short-time, high-rate notes or certificates, in hopes that a better financial season may follow.

This is even more true of municipal financing than of corporation management, and as a result we are levying a permanent tax on industry. Probably the reason that manufacture of pig iron costs more per ton now than formerly is the large interest charge; which enters into all phases of manufacturing cost. It is one of the elements in the much discussed increased cost of living. Where will it end? It is said that when Switzerland nationalized its railways, an actuary was employed, a proper sinking fund established, and in time the bonds which represented the first cost were retired. The example seems worth while. Mining companies must retire their debentures, since their raw material eventually comes to an end. Why should not manufacturing and transportation companies be held to the same requirement? It is impossible to assume that future generations will meet the obligations if there be no real wiping out of indebtedness as we go. There will inevitably be repudiation on a large scale, just as has happened a number of times in the past. In issuing refunding bonds, our financiers merely deceive themselves.

The importance of this in connection with the Steel Corporation report lies in connection with the suggestion there made that bonds may be issued to offset the cost of the new steel plant at Duluth. If this is to be generally done, we believe it will be bad policy as well as bad business. The Corporation assumed a heavy load of water when it began its career. The public has been tolerant so long as profits were going back into the business, but if new plant is to represent new debt, with a corresponding higher interest charge entering into manufacturing costs, the demand for a return to old conditions and for absolute free trade will undoubtedly receive strong stimulus. It will hit the Corporation first and will hit it hard, because the Corporation is large and conspicuous; not because it necessarily deserves punishment more than others. Probably its record, in fact, is clearer than those of most of the big corporations, and certainly it is better

than those of most American cities. Such facts, however, rarely influence the course of political action when a movement has gained headway. If the farmer pays his mortgage, why not the financier?

Sodium and Potassium Cyanides

Cyanogen is the active element in solution of gold and silver in the well known cyanide process. There would seem to be no reason why the effectiveness of the reagent chosen should not be measured by the amount of cyanogen present, unless there are conditions under which only part of it is made free to recombine. Acting on the assumption that it was all available, the sodium cyanides, because of lower price, have come into wide use with a curious nomenclature; '130 per cent' cyanide, meaning a compound having a strength of 130 as compared with the 100 of potassium cyanide. In this issue Mr. Charles Butters presents figures carefully tabulated and showing that under certain conditions, at least, the sodium cyanide fails to give the results theoretically anticipated. The source of the figures, and their completeness, set at rest any question of their accuracy. They must be accepted at their face value. The important question is whether they point to an exception or a rule, and we hope other metallurgists will follow Mr. Butters' example in sending us results of tests that they have made. A hasty inquiry develops the fact that at one large property a careful series of tests showed that because of lower extraction the sodium cyanide was not economical even if furnished free. An equally careful test made by the same metallurgist at another property showed that the value of the salt was directly proportional to the amount of cyanogen present. Evidently the character of the ore is an important matter. Neither Mr. Butters, Mr. Hamilton, nor Mr. Clennell is prepared at present to offer an explanation of why the reagents do not accomplish the result that by all known laws of chemistry should be brought about. There is a hint that other elements in the salt may or may not enter into the reaction in particular cases, but the whole subject evidently needs renewed investigation. The metallurgical world has evidently too soon settled down to the comfortable feeling that the chemistry of cyanidation was known and that mechanical improvements only were to be expected. The manufacture of the cyanides is a highly special industry calling for much technical knowledge, and now that attention is directed to the matter, important aid in solution of the problem may be expected from the manufacturers. It is their business to produce the salt that can be most economically used in each situation; a matter in which they have shown much skill. The men in the field must help by determining what the actual results of mill work are under widely differing conditions. It is not a case for jumping at conclusions, but for painstaking study of records and the making of careful tests. Send in your results as fast as they are obtained so that each may benefit by the other's experience.

Relative Efficiency of Sodium and Potassium Cyanide

By CHARLES BUTTERS

On my recent trip to my mines in Salvador, I had our consulting engineer, E. M. Hamilton, get up for me a table showing the results obtained at Divisadero upon the various kinds and strengths of cyanide that we have been using for the last seven years. There has been a continual discussion going on among our staff as to which was the best kind and strength of cyanide to use at our various mines. At our Minas Prietas works in Mexico, M. F. Perry determined that the ordinary cyanide of 99% strength was more economical for us than the 130%. This was not determined on a small scale, but after many months' run upon the same kind of ore until it was conclusively settled that the so-called 130% cyanide was more expensive for us than the 99 per cent.

I asked Mr. Hamilton to write out for me a few notes which are appended, together with the table which he compiled for me, and comment by J. E. Clennell. I am sure these figures will be of great interest and I should be very much pleased if my brother metallurgists would go through their books and make up, if possible, a similar set of figures.

It is by no means certain that the same results will be obtained everywhere, and it may be that there is something in this that every metallurgist should go into carefully. Naturally, I am obliged to face these figures for Divisadero and order 99% cyanide. I am satisfied that this will not suit the cyanide manufacturers, but if the above facts are found to be true in many places, the manufacturers of cyanide will have to meet them.

The Detailed Figures

Mr. Hamilton's table of figures is given opposite and his comment follows:

From time to time in the technical press the question of the respective merits of 'potassium cyanide 99%' and 'sodium cyanide 130%' have been brought forward. At the Butters Salvador mines and the Divisadero mine of the Butters Divisadero Co. certain small indications have lately led to a reopening of this question as far as it concerns the above-named companies.

At the Divisadero mine a table was compiled from the metallurgical sheets and store books covering the whole period during which the mill has been running, from its start in 1906 down to December 1913. During this period there has been uniform metallurgical treatment, and an apparent general uniformity in the kind of ore sent to the mill; in a word, there has been no variation in conditions apparent during this time which might reasonably account for any such differences as are shown in the table. The figures cover long periods, and it is to be noticed that on the 99% side the extractions show a large preponderance in

the nineties, whereas from the end of 1911, where the change back to 130% occurs, up to the end of 1913, the nineties are conspicuous by their absence.

In the cyanide columns there is debited against the 130% a loss of 30% plus $\frac{1}{2}$ lb. of 130% cyanide. Taking the price laid down at the mine as 17c. gold per pound of 100%, or 22c. gold per pound of 130%, this shows a loss of 30% at 17c. (or 5c.) plus $\frac{1}{2}$ lb. at 22c. (or 11c.), giving a total of 16c. per ton of ore. Add to this a loss of 3.4% on extraction, which on a head assay-value of \$6 per ton amounts to 20c., and there is a combined loss of 36c. per ton of ore, or \$3200 per month on a basis of 9000 tons.

I offer no explanation of these figures because I have none to offer, but in the light of them there is no option but to order 99% cyanide for the future. I hope that the various makers will take notice of these figures and try to shed some light thereon for the benefit of the mining industry. May I also be permitted to express a hope that in the event of an increased demand for the lower grade cyanide, they will not seize the opportunity to dilute 130% sodium cyanide down to 99% by the simple addition of sodium chloride or carbonate, but will continue to furnish a double salt containing a fair proportion of potassium cyanide, on the lines of that which used to be supplied eight or ten years ago?

What Is the Cause?

Upon this Mr. Clennell comments as follows:

In reference to the question of difference between so-called '99% potassium cyanide' and '130% sodium cyanide' I have never investigated this point on a working scale, but have on several occasions made small-scale experiments in which the invariable result has been to show that solutions containing equal amounts of cyanogen give identical results, whatever the nature of the metal with which it is combined. It is quite possible that in a particular ore the presence of sodium chloride or sodium carbonate may be beneficial. Not knowing all the circumstances, it is impossible to say whether the difference shown in Mr. Hamilton's figures is really due to the different brands of cyanide or to some other cause.

Tungsten ores were produced during 1913 in six of the western states, Colorado, California, Idaho, Arizona, South Dakota, and Nevada, according to Frank L. Hess, of the U. S. Geological Survey. The output for 1913 was equivalent to 1525 tons of ore carrying 60% of tungsten trioxide (WO_3), and was valued at about \$640,500. The production in 1912 was 1330 tons, valued at \$502,158. Boulder county, Colorado, produced 953 tons of ferberite during 1913.

*Sodium cyanide 120%.

NOTE.—The months left blank are those in which both kinds of cyanide were used in the plant.

Functions of a Mint

It is quite a fallacy to imagine that a mint can ensure the circulation of gold in a country. In many a European country where a gold mint exists, gold currency is conspicuous by its absence. The mint no more performs the operation of supplying currency than the atrophied eyes of fish in the Kentucky caves perform the action of sight, according to Samuel Montagu & Co. of London. The essential function of

a gold mint is to provide for the internal needs of the country that sets it up. Unless that country possess the power to put gold coin to common use, the only circulation would be similar to that which ensued when the daughters of Danaus, of ancient mythology, were condemned to pour water into a cask with no bottom, namely, a circulation not in, but outside the cask. If a country possess a balance of trade in its favor, and be suited by custom and individual wealth to handle gold coin, a gold mint becomes a useful adjunct to its currency system.

Ore Treatment at the Prestea Block

By HUGH F. MARRIOTT

*This mine is situated in the Gold Coast Colony, West Africa. It is provided with three shafts. The main shaft is equipped with a steel head-frame containing two jaw-crushers, and is served by a direct-acting steam hoist. At the north shaft hoisting is done by an electric main engine and an electric sinking and main engine. An aerial ropeway conveys ore as broken in the mine from shaft bins to crusher station.

The crusher station has a bin capacity of 470 tons and is equipped with three electrically driven jaw-crushers, each capable of crushing 40 tons per hour. From the foot of the crusher station the ore is again elevated by an aerial ropeway to the level of the top of the mill and is dumped into the mill bins. The mill bin capacity is 1550 tons, thus making the total bin capacity on the surface 2600 tons, or, at 25,000 tons per month, three days' supply.

The mill consists of 110 stamps, and crushes an average of 8.6 tons per stamp per 24 hours through 10-mesh screens. Grading tests have been made on ore taken from the bins to ascertain the effect of the fine material on the subsequent treatment processes. There is not yet sufficient evidence that any variation of procedure at this stage will be of advantage. The pulp from the mill is collected in a launder and conducted to the Cobbe-Middleton pan house. Following on the suggestion of W. R. Feldtmann in his recent report, a set of spitzluten is being erected at this point to relieve the pans of the material which does not require finer grinding. This will now pass directly to the amalgamating tables. The experimental tests indicate that by this means the whole work of regrinding can be accomplished by 70% of the pan equipment. The surplus pans will thus constitute a useful standby. An automatic sampler has also been introduced immediately below the mill, and is designed to give an accurate record of the total gold content of the material passing from the mine into the reduction plant. This will be further dealt with later on. The coarser material from the mill is further crushed by the pans to a plus and minus 60 product. The reground material from the pan-house flows to the amalgamating tables, the concentrate clean-up from each pan having been first subjected to amalgamation in one locked pan, which is specially used for this purpose. The remaining coarse sand which passes the pans is separated in spitzluten and sent to three Bigelow pans and thence returned with the main product to the amalgamating tables. These are apportioned as required to the coarser or finer products. They have hitherto been run as shaking tables, but experiments are now being made to see if they will not catch an equal amount of gold as fixed tables and thus save much of the attention and cost of upkeep. The preliminary experiments have

been successful as far as the finer material is concerned, but the tables containing the coarser material were found to scour. This difficulty should disappear when the hydraulic separation and secondary regrinding equipments are installed and adjusted.

The gold caught by amalgamation constitutes 56.8% of the total product. The pulp is again classified hydraulically, and then passed over Wilfley concentrating tables. The concentrate goes to roasting furnaces and the tailing to the cyanide vats. The tendency is to increase the amount going to the roasters, as it is considered that a better extraction and greater profit are obtained by this system. The roasted ore is fed into Bigelow pans, where it is both amalgamated and treated with cyanide at the same time, and, after being subjected to further agitation and cyanide, is filter-pressed and the solution passed through a zinc-box. The concentrate going to the roasting department is more than can be dealt with by one furnace, but when the new one is installed the capacity of the plant should be adequate. The gold recovered from the roasting department is 18% of the total product, and the extraction by this process is 95%. The tailing from the Wilfley tables runs into collecting tanks and is then transferred to leaching vats by belt-conveyors and subjected to ordinary treatment. The gold recovered in the cyanide plant is 6.2% of the total product, and the extraction by this process is 34%. The sand residue assays about \$1.62 per ton. The tailing is removed by cars running under the vats, and the quantity required for refilling the stopes in the mine, about half the total output, is drawn to the heads of the various filling passes by locomotives, while the remainder is run out to tailing dumps by hand labor. Owing to the increasing distance of dumping points on level ground, the disposal of tailing by the present method has become inconvenient and expensive, and arrangements are being made to elevate the cars on an incline plane by mechanical haulage, thus bringing into use a large area of dumping ground much nearer the cyanide works. The slime, which is separated out above the Wilfley tables, runs into the slime pond and remains untreated. It is estimated to contain about \$2.40 per ton of dry slime. Various experiments have been made from time to time on this product with a view to recovering a profit therefrom. The most recent have been to pass the slime over a concentrating table and to agitate the concentrated product with cyanide. Experiments have also been made in agitating the whole of the slime with cyanide without separating out the concentrate. The increased extraction obtained by concentration does not justify the extra cost of installing and running the necessary plant. It has therefore been decided to proceed on the lines of dewatering the slime as far as possible and to treat the whole of the dewatered material with cyanide in agitating vats. The experiments in this direction have resulted in a recovery of 96c. out of a total gold content of \$2.40 per ton of dry slime.

*Abstract from a report made on the property in 1913.

Hydraulicking on the Klamath River

By J. H. THELLER

The débris law does not affect Siskiyou county, as the drainage is directly westward to the Pacific ocean, hence hydraulic mining in this county is still carried on.

The River Bend mine is on the Klamath river, 25 miles west from Hornbrooke, 25 miles north from Yreka, and 15 miles east from the junction of the Klamath and Scott rivers. The prevailing rocks of the country in that vicinity are granites and schists. It is the former that largely contributes so many rich pockets to the prospector. The deposit which is being mined is an ancient channel of the Klamath river, running nearly parallel to its present course, but lower than it. From the work already performed, the old channel shows a width of 100 ft. from rim to rim, although prospect drifts run at intervals of 600 ft. ahead of the work failed to reach the inner rim. The prospect work had to be discontinued owing to bad air, hence no definite results were obtained, although indications point to the widening of the channel.

Character of Bedrock

The bedrock is a hard schist, very rough and water-worn, with a general dip to the southeast. Soft streaks of black shale are encountered at intervals. This shale is highly tilted, forming an excellent stopping place for the gold already caught. In cleaning this shale it is found advisable not to strip it clean with the giant, but to have men pick it at right angles to the dip to a depth of about two feet. If it be washed clean with the giant or taken up parallel to the dip, the gold sinks deeper and is lost. The hard bedrock is different; it may be piped clean, the crevices only being cleaned by hand. Where this soft bedrock occurs, large quantities of gold are found. In the centre of the channel the bedrock is high and very hard, falling off abruptly on either side about six or eight feet, where it again rises forming the rims. At the contact of the hard schist and shale there is a blue clay separating the two. This is termed 'sluice robber', as any gold contained in or picked up by it will be carried through the sluices. We have experienced no trouble in handling it, since the clay is entirely broken up when hit by the stream of the elevator, thus delivering any gold contained therein to the riffles.

The bedrock is, on an average, at a depth of 30 ft., the best gravel occurring within 5 ft. of the bottom, although the pay-streak has an average depth of 10 ft. The gravel-gold is much lighter in weight than the bedrock-gold, although the former has a greater fineness than the latter. Resting on the pay-streak is a gravel of finer texture, but of poorer grade. Topping this is overburden. The entire mass constitutes a bank about 30 ft. high.

The pay-gravel is dark blue in color, and consists of

heavy, well rounded rocks, together with much wash. It has a shingled appearance while in place, contains medium sized boulders, the largest of which weigh from 500 to 1000 lb. 'Bulldozing' has been found more economical than moving them with a derrick. All boulders larger than 10½ in. diameter must be broken, or thrown aside on a clean strip of bedrock, as the size of the elevator throat is 10½ in. Black sand forms but a small part of the gravel. Although the degree of concentration is not definitely known it will approximate one-quarter of a pound of black sand per cubic yard of gravel. Assays of it show no platinum, and it is valueless except for the free 'flour gold' which it contains. Sulphide minerals, such as cubical iron pyrite and arsenopyrite, which occur in the gravel also mineralize the bedrock. They assay \$18 per ton, but no attempt is made to save them. It is chiefly due to these sulphides that the pit-water, or water flowing from cracks in bedrock, is heavily charged with arsenic. This water attacks all parts of metal with which it comes in contact, so that it is found necessary to paint with asphaltum all pipe-lines, parts of the elevator, and other pieces of metal which are in contact with the pit-water.

Water Supply

The water supply is from two separate sources. The system includes 11 miles of ditch and 1½ miles of flume. The ditch supplying the two giants and the 8-in. Evans water-lift brings the water from Dogget creek, two miles east of the mine, and delivers it to a penstock 115 ft. above the works. The ditch carries an average of 350 miners inches. The pipe-line at the intake is 22 in. tapering to 13 in.; branches feeding the giants are 11 in.; the branch supplying the lift is 11 in. tapering to 9 in. The water-lift is used only in case of an emergency, such as the choking of the elevator. The elevator-water is brought from Buckhorn creek, ten miles to the west. The main ditch is 4 ft. on the top, 2½ ft. deep, and 2 ft. wide on the bottom. The grade is ⅝ inch in 16½ ft. It will convey 700 miners inches of water, but only carries 375 at the present time. The water is delivered a distance of two miles to a point 2000 ft. above the property. From there it is conveyed down the mountain through a flume for one mile, discharging into a gulch which takes the water the remaining distance. It is caught by a dam 375 ft. above the mine, from which it flows to a penstock, and thence through a pipe-line to the elevator. The pipe at the

intake of the penstock is 24 in. diameter, tapering to 11 in. at the nozzle of the elevator. The length of the pipe-line is 1040 ft. Slip-joint pipe is used until water-level is reached, and flanged pipe from that point to the elevator.

There are two giants (No. 2 Joshua Hendy) in operation. They consume approximately 350 miners inches of water, working at an effective head of 90 to 100 ft. Three and three and one-half-inch nozzles are used. One of the giants is used to cave the gravel, the other to drive it to the elevator. The elevator is one of the Campbell type, having a 3½-in. nozzle, a 10½-in. throat, and a 14-in. upcast pipe. It uses 375 in. of water under an effective head of 325 ft. It is set in a sump 10 ft. deep, in bedrock. The sump is six feet square at the collar, tapering to four feet at the bottom. The elevator is set at an inclination of 70°. The height of elevation is 46 ft. vertically from the top of the nozzle to the top of the blocks in the head-blocks, insuring sufficient dump to the river. It may be stated in passing that no trouble is experienced with the tailing after the current of the river is reached.

The following table is made up from daily averages throughout the season of six months during 1912-1913:

| | |
|--|----------|
| Cubic yards of gravel washed per day..... | 417.00 |
| Miner's inches of water per day (24 hr.)..... | 350.00 |
| Cubic yards of gravel washed per miner's inch..... | 1.19 |
| Cubic feet of water per cubic foot of gravel washed. | 67.00 |
| Cubic feet of giant-water to be lifted per minute... | 525.00 |
| Cubic feet of seepage water to be lifted per minute. | *45.00 |
| Total flow in elevator upraise-pipe, cu. ft. per min.. | †1132.00 |
| Cubic feet of gravel to be lifted per minute..... | 7.81 |
| Height of banks, feet | 30.00 |
| Grade of sluices, inches | 7 to 12 |

*Estimated.
†Elevator feed-water, 375 miner's inches.

The following table is the average working cost per yard throughout the season, administration charges not included:

| | Per day. | Per cu. yd. |
|---|----------|-------------|
| Foreman and common labor..... | \$17.50 | \$0.041 |
| Freight, supplies, etc..... | 1.00 | 0.002 |
| Boarding-house | 5.85 | 0.014 |
| Maintenance, including all dead work..... | 3.22 | 0.008 |
| Depreciation of plant, ditch, riffles, giants, etc. | 6.66 | 0.015 |
| Total working cost | \$34.23 | \$0.080 |

In the above table is shown the duty of the miners inch of water per 24 hours in the carrying of the gravel from the giants to the elevator only. I have limited the discussion to this in the belief that it is improper to charge the carrying capacity of the total water used with that portion of the work of transportation performed in and beyond the elevator itself: first, because the giant water has a 'carrying duty' only between the giant and the elevator. Thereafter it becomes 'freight' and has to be itself carried as dead weight along with the gravel; second, at the elevator additional 'freight' is presented in the shape of seepage water that enters the cut in large quantities and has to

be carried away. These two bodies of water, giant and seepage water, comprise the real load that consumes the water for the elevator, and we seldom deliver enough gravel at the elevator to reach the carrying capacity of the elevator. Therefore, the duty of the miners inches from the giant to the elevator is the important consideration and if the elevator carries the water from its giant it will handle any amount of gravel the water contains whether it be large or small, although an excess of sand will choke the elevator.

At the beginning, after setting the elevator, the gravel bank being close, all gold is caught in the upper sluices. As the work progresses and the gravel bank becomes farther away a bedrock flume is necessary. The first box is set so that its end is 3 in. above the nozzle of the elevator. This sluice is 20 in. wide on the bottom, 24 in. deep on the sides, and is set at a grade of 7 inches in 12 ft. To overlap the joints of the bottom boards of the sluice, false bottoms are put in. Upon these rest the riffles, held down on the sides by 2 by 4-in. scantlings. The sluice-boxes are built in 12-ft. lengths of 1¼-in. yellow pine boards. They are riffled longitudinally and also laterally. The longitudinal riffles are 20-lb. rails, flanged down, spaced with slip-blocks, giving a 3½-in. riffle space on top. These rails give an ideal surface over which boulders can travel. The cross riffles are pine blocks 4 in. high, spaced 2 in. apart. In the second box from the head, Hungarian riffles are kept. They are taken up every three days. It is easier and quicker to handle them than the longitudinal or block riffles. Eighty per cent of the gold recovered is caught in the bedrock sluice and the elevator sump.

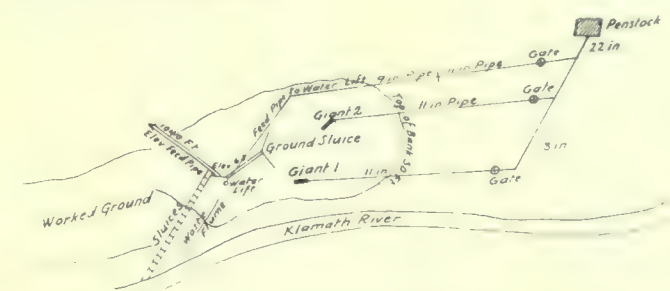

FIG. 1. PLAN OF WORKINGS.

The elevator raises the gravel to the upper sluices and through them it runs to the river. The head box is 6 ft. high, 12 ft. long, tapering from 48 to 32 in. The bottom boards are 1½-in. yellow pine covered with 1¼-in. false bottoms of the same material. In addition, back and top are made of 1¼-in. lumber, lined with ¼-in. steel plates. It is yoked on the sides every three feet with 4 by 4-in. timbers. A slightly curved hood of cast iron, 4 ft. long, 30 in. wide, and 4 in. thick, is bolted to the top of the box. This stops the upward trend of the water and gravel, directing it down the sluiceway.

The sluices are built in separate units. Each box is 12 ft. long, 32 in. wide, and 24 in. high. They are set on a grade of 6 inches in 12 ft., and are built of 1½-in.

GIANTS, SLUICES, AND BEDROCK AT RIVER BEND.

yellow pine lumber, yoked every 4 ft. with 3 by 4-in. yokes.

The bottom of each box is covered with a planed false bottom, down to and including the eighth box. The false bottom for the other 12 boxes are of unplanned lumber.

Owing to the wear of the constantly falling boulders on the bottom of the head-box, blocks 12 by 12 in. were used. These were built close together with no

FIG. 2.

rifle space between the sets (Fig. 2), no attempt being made to save gold in this box. From the head-box to the first box in the sluice there is a drop of 3 in. The blocks in this space, together with the succeeding four boxes are 9 by 9 in. Experiments showed better results by spacing the blocks 1 in. apart in each set and separating each set by 2 in. This gives a longitudinal as well as a lateral riffle. The longitudinal space between the blocks is staggered. This is accomplished by varying the widths of the first block in the set (Fig. 3). This style continues for the next three boxes.

FIG. 3.

There is a drop of 3 in. to the box containing the Hungarian riffles. These are angle-iron sections running laterally across the sluice. They are bolted to iron strips which tie a set of the bars together. Each of these sets is 2 ft. long, and contain eight bars, thus producing a riffle space of 3 in. (Fig. 4).

This type continues for two boxes where a drop of 2 in. brings the material onto the longitudinal rails. These are of the same kind already described in the ground-sluice. The space at the top is 3½ in., nine rails to the box (Fig. 5 and Fig. 6). These continue for two boxes, where again one box of block riffles is placed. This takes us to the tenth box. From here to the end, gold becomes so scarce that it hardly pays to clean up. From the tenth box to the twentieth and last, old rails, scrap iron, and the like, and placed on the bottom of the boxes to save wear. Quicksilver is used from the fourth to the tenth box. It is an interesting fact to note that in a set of boxes, 25% of the gold is caught in the different sudden drops from one riffle to the next lower one.

Most of the gold is caught in the fourth, fifth, and

sixth boxes. From there on the quantity falls off rapidly. Beyond the tenth box it is not economically saved, hence attention and labor may well be directed

FIG. 4. ARRANGEMENT OF RIFFLES.

elsewhere. The reason more gold is not caught in the first three boxes may be explained by the fact that the gravel is given such momentum by the elevator that two or three boxes are required for the separation

FIG. 5.

FIG. 6.

of the different particles according to their respective specific gravities, and in order to allow the particles to fall with the riffles.

Costs at the Simmer & Jack Mine

During the past fiscal year there was treated 912,200 tons of ore, yielding 230,644 oz. fine gold at the following cost:

| | Per ton. | | Per ton. |
|-------------------------|----------|------------------------|----------|
| Development | \$1.60 | Sand treatment | \$0.20 |
| Mining | 0.04 | Slime treatment | 0.13 |
| Ore transport, sorting, | | General expenses | 0.23 |
| crushing | 0.08 | Equipment | 0.02 |
| Stamping | 0.22 | | |
| Tube-milling | 0.12 | Total | \$2.64 |

Two blast-furnaces are working regularly at Katanga, Tanganyika Concessions, Central Africa, producing 1000 tons of copper per month. It has been decided to erect four more furnaces.

The Brown Patents Decision

The decision in the United States Circuit Court of Appeals for the Third Circuit on appeal from the District Court of the United States for the District of Delaware, of the case of Joseph A. Vincent, owner of patent 781,711, granted to Alden H. Brown, February 7, 1905, for a process of treating precious metal bearing ores, and charging the Tonopah Mining Co. and others with infringing the two claims thereof, was handed down last week. The judges were Messrs. Gray, Buffington, and McPherson, the ones who decided the Moore-Butters controversy, and the following opinion was written by Mr. Justice Buffington.

Specifications of the Patent

Brown's patent, as recited in the specification, "relates to a process for the treatment of precious metal bearing ores, and embraces the treatment of the ore by a solution of cyanide of potassium or of other alkaline cyanide and the subsequent treatment of the ore by concentration." The specification states that: "It has been the practice for many years in plants where the concentration and cyanide processes are used in combination, to treat the ore, first, by concentration, and, secondly, by cyanide. The process which I have invented and which I now have in successful operation is a reversal of this proceeding with the addition of certain special features in connection with the cyanide step."

The second or broad claim is for these two steps in succession, to wit: "2. A process of treating sulphide ore consisting first in subjecting the raw or unroasted ore to the action of a cyanide solution whereby the finer metallic values are dissolved, and second, subjecting the ore or tailings to concentration whereby the coarser values are recovered."

The first claim also includes the two foregoing steps, but "certain special features in connection with the cyanide steps," are detailed in the claim, which is: "1. The herein described process for the treatment of ore consisting in first pulverizing the ore in the presence of cyanide solution; second, subjecting the ore to hydraulic classification by the introduction of cyanide solution at the bottom of an overflow tank to produce an ascending current; third, leaching the ore by the use of cyanide solution whereby the finer values of the ore are dissolved; fourth, removing the dissolved metallic values from the ore in any suitable manner; and finally subjecting the residue of ore to concentration."

The cyanide process, which process is described in *Moore v. Tonopah*, 201 Fed. Rep. 532, a case in this court, consists in subjecting metal-bearing ores to cyanide of potassium dissolved in water. The result is that the metal is disengaged or dissolved and is carried in solution. Such solution is then removed from the residue of the ore by percolation, filtering, or decan-

tation, and is ultimately subjected to electro-chemical action whereby the precious metal is precipitated.

On the other hand, concentration is a mechanical process of removal. It is usually done on concentration tables. Such tables are slightly inclined and have grooves, across which the finely divided ore is slowly carried by a shallow current of water, the table being given a jerky reciprocating motion. The result is that the heavy constituents work along and run over the edge of the table at different places from the lighter ones. It will thus be seen that the two processes of cyaniding and concentrating are distinct, well known, and operatively different, one being chemical, the other mechanical. As noted by the patentee, it was usual to concentrate first and cyanide last, and the patentee advised a reversal of this process. His object in so doing, he states, was because where concentration was used in advance of cyaniding there was a large loss in values by reason of the fact that the necessary water treatment in connection with the reduction of the ores to a fine state of division resulted in a taking up by the water of a large percentage of ore values. As a result it was "difficult, if not impossible, to settle these values for further treatment within the limits of a plant of ordinary construction, for the reason that in the case of many ores these slime values remain in suspension for many hours. It will therefore be understood that in the case of ores of this sort, if amalgamation, concentration, or other process involving the use of water for crushing or treatment is used preliminary to the cyanide process, it will be necessary to have a very extensive system of settling tanks in order to recover these suspended values and hold them in the mill, so that they may be subjected to further treatment. It is a well known fact that the cyanide process recovers only the fine values, and in the treatment that I have devised these fine values are recovered by the cyanide process in the beginning, leaving only the coarser values which are readily recoverable by concentration, the latter being specially adapted for saving this class of values."

No New Principle

It will be noted that no new principle of operation, either in cyaniding or concentrating themselves was disclosed in this patent. It was at most simply a more effective treatment and it will thus be seen that transposition of concentration from initial to final stage, and of cyaniding from final to initial stage is the substantial disclosure of this device. Assuming, for present purposes, that this change was original with Brown, and that it involved invention it must be conceded the field of invention was narrow, and Brown's claims should not by construction be enlarged to include within infringing fences processes which were not within the

field of his inventive disclosure. Now without entering into details, it suffices to say that the second claim embodies the two elements, of, first, cyaniding, viz., "subjecting the raw or unroasted ore to the action of a cyanide solution whereby the finer metallic values are dissolved"—and second, "concentration, whereby the coarser values are recovered." This claim is perfectly clear. A reading of the patent shows precisely what the patentee disclosed, and the claim as precisely claims that disclosure. There is no ambiguity in either disclosure or claim. They are self sufficient and self explanatory. The first element is the use of the well known cyaniding process as the initial and finished first step of the process.

The First Step

The specification thus unmistakably refers to both the initial use and also the completion of cyaniding in this first stage of Brown's process. Thus, "My invention relates to a process for the treatment * * * by a solution of cyanide of potassium * * * and the subsequent treatment of the ore by concentration. * * * It has been the practice * * * to treat the ore first by concentration, and secondly, by cyanide. The process which I have invented * * * is a reversal of this proceeding. * * * If * * * concentration * * * is used preliminary to the cyanide process, it will be necessary to have a very extensive system of settling tanks in order to recover these suspended values and hold them in the mill, so that they may be subjected to further treatment. * * * In the treatment that I have devised these fine values are recovered by the cyanide process in the beginning, leaving only the coarser values, which are readily recoverable by concentration." The drawings illustrate a wet crushing plant. "I will say, however, that so far as the broad idea of employing the cyanide step previous to concentration is concerned, the advantage in this respect would be equally great if dry crushing instead of wet crushing were employed. * * * From the tanks *I I* the gold-bearing solutions pass to the zinc boxes *J, J*, where the values are precipitated. * * * After the cyanide treatment has been completed, the sand tailings from the leaching tank *G* are transferred * * * to the tailings bin *P*. * * * The mixer *K* distributes the tailings to the concentrating table *L*." These extracts show that all steps prior to the sand tailing reaching the concentrating table, concerned cyaniding and cyaniding alone. Indeed the cyaniding of Brown's process had, at this stage, done all that cyaniding was intended to do. In other words, it had resulted, as cyaniding ordinarily did, in "The gold-bearing solutions pass(ing) to the zinc boxes *J J*, where the values are precipitated."

The Second Step

Following this completed process of cyaniding came the second step of the claim, namely, "subjecting ore or tailings to concentration where the coarser values are recovered." Concerning this step there is no ambiguity. It simply takes the sand tailings, which the

finished cyanide process had left in the mixer *K*, and concentrates them. Cyaniding has finished its assigned work and recovered its share of the metal product. The sand tailings were the by-product of cyaniding. It was on this by-product that concentration took up its part of the process. Concentration was so well understood that the patent simply says:

"In regard to the matter of concentration, I will say that any desired system may be used, either the standard practice * * * or any of the more recent oil-concentrating processes, in which the affinity of certain oils for metallic sulphides or other valuable minerals is made use of in order to effect the proper separation."

The first claim is based generally on these two elements, viz., cyaniding and concentration, but embodies in the cyaniding step those "special features in connection with the cyanide step," which the patentee disclosed and thus claimed. As we read that claim the first four elements, viz., "pulverizing the ore in the presence of the cyanide solution; * * * subjecting the ore to hydraulic classification by the introduction of cyanide solution at the bottom of an overflow tank to produce an ascending current; * * * leaching the ore by use of cyanide solution whereby the finer values of the ore are dissolved; * * * and removing the dissolved metallic values from the ore in any suitable manner"—all these are specific sub-steps of cyaniding—those "certain special features in connection with the cyanide step," as the patentee aptly says. They culminate and effect cyaniding. Unitedly they are the same as the first and broader stated first element of the second claim, viz., "subjecting the raw or unroasted ore to the action of the cyanide solution whereby the finer metallic values are dissolved." It follows, therefore, that all the four first elements of the first claim are to be treated as agencies culminating in cyaniding, and so regarding them it follows that however much some other process may utilize one or more of these elements, if they are not made use of in a process that culminates in and completes cyaniding as its first and pre-concentrating step, such element or elements are not employed to infringe the cyaniding initial step of these two claims.

The Third Step

We here note that the discussion of this case seemed to centre on what was meant by the third step, "leaching the ore by the use of cyanide solution whereby the finer values of the ore are dissolved," and the fourth, "removing the dissolved metallic values from the ore in any suitable manner." To us these are plain. Leach is a word of recognized import, namely, to cause a fluid to percolate through. Brown's leaching was by the cyanide process, namely, "leaching the ore by the use of cyanide solution," and the other words, "whereby the finer values of the ore are dissolved," merely state the result of such percolating or leaching. What was meant by leaching was well understood in the art. It was thus described in *Moore v. Tonopah*, supra,

"The cyanide ore process came into use about 1887 and is the real foundation of the tremendous increase in gold production in the last two decades. It is now the prevalent method of treatment. In it the ore is first crushed and then placed in tanks containing a solution of cyanide of potassium. This solution percolates through the crushed pulverized mass, and, being a solvent of gold, carries off such gold as is subjected to its action. This is called "leaching" and any crushed ore through which percolation took place was termed "leachable." As the term was thus well understood in the art, we are justified in giving it that meaning in this claim. So doing, it follows that the fourth step, which "removes the dissolved metallic values from the ores," merely removes the metallic values which the leaching has dissolved.

No Infringement Shown

This two staged process—first cyaniding, next concentrating—being the only disclosure of Brown and the claims embodying those two separate, individual, completed stages or steps, it follows that any process which makes concentration an intermediate and completed step, one that precedes final and effective cyaniding, is a process different from the one Brown disclosed and claimed. Measuring the defendant's process by these standards, it follows that infringement is not shown, for, without entering into a detailed description of its plant, it suffices to say that a study of its workings has brought us to this conclusion. The defendants, in common with Brown, it may be conceded, are using the cyanide solution in the earlier stage of their process, and to that extent we may say initially utilize the general chemical treatment incident to cyaniding, preparatory to concentrating. But beyond this the resemblance ceases, for by defendant's process concentration—"effective, finished, and final"—is the initial and intermediate step in their process. At such intermediate step the fruits of concentration are withdrawn from the process, and this first completed step of the process, the one "whereby the coarser values are removed," is, as we have seen, the second step of Brown's process.

Differences in the Two Processes

After the defendant's concentration is finished, the by-product goes forward to be subsequently treated by a protracted process of cyaniding. This is at variance with Brown's process in three respects, first, cyaniding follows concentrating; second, it is a system condemned by Brown and one he sought to avoid in that where "concentration * * * is used preliminary to the cyanide process it will be necessary to have a very extensive system of settling tanks in order to recover these suspended values and hold them in the mill so that they may be subjected to further treatment;" third, the defendant's process which physically withdraws from the operation of the process the products of concentration in advance of withdrawing those of cyaniding, makes the process one avoided by Brown, viz.: "It is a well known fact that the cyanide process re-

covers only the fine values, and in the treatment that I have devised these fine values are recovered by the cyanide process in the beginning, leaving only the coarser values, which are readily recoverable by concentrating, the latter being specially adapted for saving this class of values."

It is apparent, therefore, that the defendant's device, which the proofs show has been of great practical worth, owes its worth to the fact that it is built and operated in express disregard to the instructions of Brown's patent. Without passing on the question of the validity of that patent, it suffices to hold defendants do not infringe. The decree below is therefore reversed, and the case remanded with instructions to dismiss the bill for non-infringement.

Treatment of Tailing at Butte Reduction Works

By BANCROFT GORE

Adjacent to the abandoned smelting works of the Colusa-Parrot Mining & Smelting Co. at Butte, Montana, which was one of the W. A. Clark properties purchased by the Anaconda company in 1910, is a large accumulation, estimated at close to a million tons of tailing from the concentrator, containing a gross value in silver and copper of more than \$3,000,000. This valuable dump was retained by the Clark interests pending thorough investigation by a large staff of testing engineers, making use on a large working scale of the latest developments in hydro-metallurgy and ore dressing. One section of the old concentrator not destroyed by fire was remodeled and fitted with every known device that might throw light upon the commercial treatment of this tailing. Preference was finally given to the oil flotation process rather than roasting and leaching as at Anaconda with similar material, and elaborate mill tests were made under supervision of the Minerals Separation American Syndicate Ltd., using a 50-ton agitation unit where a high recovery of the sulphides was demonstrated. One factor in favor of the process was the extreme simplicity of the operations. The raw tailing was fed directly to a Hardinge tube-mill and after crushing to pass 60-mesh screen entered the flotation unit where a remarkably clean high-grade product was removed, dried, sampled, assayed, weighed, and shipped for treatment to the Anaconda smelter. As the tailing has been exposed to weathering, a part of the copper occurs as oxides, sulphates, and basic sulphates, which will be recovered by a preliminary treatment with weak sulphuric acid solutions. The tube-mills are to be lead-lined on this account. A plant with initial daily capacity of 1000 tons has been designed and will be in operation before 1915.

Mining in Norway employed 6508 men and women at 60 properties during 1911.

A Screw Classifier and Fine Ore Feeder

By S. A. WORCESTER

A number of the classifiers here described are in use in a mill of my recent design and construction, and while they develop much larger capacity (about 100 tons each per day), than other machines, their initial cost and space required per unit of capacity are also much less. The screw has more than one-third of its length completely submerged and this feature effects movement of a large volume of pulp in proportion to the diameter of the screw. The screw being in the form of a ribbon, the finer material rises from the sand and follows backward over both the outer and inner edges of the ribbon, while the coarser material remaining nearer the bottom is propelled onward to the discharge. These classifiers operate in closed circuit with tube-mills and the solution necessary for maintaining about 40% moisture in the mill feed is supplied in a number of small streams along the upper end of the screw. This accomplishes active separation of sand from slime and aids rapid classification. The sand is spouted direct to the spiral feed of the tube-mill and the tube-mill discharge is returned by an air-lift to the classifier. The submerged thrust bearing of the classifier screw has a small flow of mill solution passing through it, thus preventing slime from entering and destroying the bearing. The board A, bolted to the front of the cast iron discharge box, determines the height of the slime level in the classifier, and to a large degree the fineness of the slime discharged. Chips floating in the space between the ore feed and the slime discharge are arrested by the screen B, and are skimmed from the surface occasionally with a wire-cloth skimmer.

The feeder conveyor shown delivers material 90% of which will pass 10 mesh, from 200-ton bins to the classifiers, and has proved exceptionally reliable and satisfactory in operation. Features of interest include the combination of the functions of feeder with those of conveyor and ele-

vator, if this should be desired. It can be given an upward inclination of probably 30° when running at very slow speed, thus gaining mill height, whereas most feeders involve loss of mill height and perform but one function. Simplicity and inexpensive construction characterize this feeder, and the ease and accuracy of the screw gate adjustment are important. I regard the constant stream of ore given by this feeder as more desirable than the intermittent feed given by any type of reciprocating or disk feeder, and I believe the constant stream tends to produce more uniform and dependable action in the machines which it feeds. In the arrangement of machines which I show, and which has been very satisfactory, the classifier is driven by a quarter-turn belt from the tube-mill countershaft, and the feeder by a crossed belt from the classifier countershaft.

It is essential in the prevention of mine fires that rubbish be not allowed to accumulate in the vicinity of buildings or timbering and that the supply of hay be properly protected from fire. Do not construct wooden buildings nearer than 200 ft. from the mouth of the tunnel unless they are absolutely necessary. In such a case provide a separate exit at least 200 ft. from the tunnel and arrange a fire door so that the regular exit may be closed from a distance in order that the men in the tunnel may not be suffocated by smoke and gases in case that the buildings take fire. In either case, provide for a water-supply adequate for fire protection.

Smelting of Ores and Metals

*With the view of developing more efficient methods in the smelting of ores, the bureau began at its Pittsburgh experiment station a detailed investigation of the practicability of using the electric furnace as a substitute for or adjunct of the blast-furnace, with particular reference to the treatment of low-grade ores. One problem studied is the possibility of using crude oil as a reducing agent. The results of these experiments, which were made by J. F. Cullen under the direction of D. A. Lyon, were incorporated in a report for publication. Another problem, still under investigation, is the possibility of using the electric furnace in the smelting of copper ores, especially sulphides. The experiments incidental to this investigation included work on:

1. The smelting of copper concentrates. Experiments have been made to determine to what degree loss of copper in the slag could be lessened by smelting these concentrates in an electric furnace.

2. The use of the electric furnace in the smelting of non-ferrous ores. The purpose of this investigation is to determine the feasibility of using electricity as a source of heat in smelting copper-iron sulphide ores, lean zinc and lead ores, and in fact all low-grade ores that are not amenable to treatment by wet methods, and especially to ascertain whether the electric furnace may be used profitably for treating ores from deposits that are so far from a smelter that transportation charges exceed the value of the metals in the ores. In some cases it may be possible to use hydro-electric power in an electric furnace, thus removing the necessity of transporting worthless gangue, and enabling the metals of the ores to be transported as matte or crude metal, providing it was not feasible to refine the metal at the smelting plant.

3. The use of the electric furnace as an aid to the ordinary blast-furnace. In the study of this problem the following points have been considered: (a) the possibility of recovering the iron in the slag as metallic iron—at present, as is well known, although the iron content of a gold, silver, copper, or lead ore may be large, it goes to the dump in the slag, either as iron oxide or iron silicate; (b) the possibility of producing ferro-silicon from the slags ordinarily obtained in smelting non-ferrous ores; (c) the recovery of the sulphur as a by-product in the smelting of sulphide ores; (d) the discovery, if possible, of some suitable collector or carrier other than copper and lead for the precious metals in smelting practice.

The purpose of the work has not been to show that the electric furnace should replace reverberatory or the blast-furnaces, but that in some places it may be substituted for them. So far only the possibility of treating copper sulphide ores has been studied. The

results of the work will be published in a bulletin. The electric furnace work for these investigations has been done by R. M. Keeney, under the direction of D. A. Lyon.

New investigations proposed for the coming year include: The electric smelting of zinc ores; the smelting of titaniferous iron ores; the production of 'natural alloys'—that is, the production from complex ores of alloys containing different metals in such proportions as to be of commercial use for structural materials, for tool making, etc.; the use of an electric process for removing moisture from the blast supplied to blast-furnaces; the removal of sulphur from producer gas for metallurgical purposes.

The following reports have been or are being prepared for publication: 'The Use of the Electric Furnace in the Manufacture of Iron and Steel,' by D. A. Lyon and R. M. Keeney; 'The Use of Crude Oil as a Reducing Agent in the Reduction of Iron Ores,' by D. A. Lyon and J. F. Cullen; 'Smelting of Fine Michigan Copper Concentrates in the Electric Furnace,' by R. M. Keeney; 'The Use of the Electric Furnace in Metallurgy,' by D. A. Lyon, R. M. Keeney, and J. F. Cullen; 'The Possibility of Smelting Copper Ores in the Electric Furnace,' by D. A. Lyon and R. M. Keeney.

OFFICE OF BUREAU OF MINES AT WASHINGTON.

*From the forthcoming third annual report of the National Bureau of Mines, Joseph A. Holmes, director.

Suggested Method of Standard Screen Tests

By LLOYD ROBEY

The metallurgist of today is turning his attention more and more to the problem of treating low-grade ores at a profit, and in localities where this problem has been solved, to the unending one of gaining the last possible penny of profit. In the effort to solve these problems he demands of the laboratory, in its tests and experiments, a close approximation to actual field conditions, and a standardization of laboratory processes, so that he may have as fair a basis of comparison as possible.

This demand for methods of laboratory investigation which will give not only exact but comparable tests of the work of different machines under the same conditions, or of the same machine under varying conditions, has not been entirely met as yet. In particular, the general practice in making screen tests is far from uniform. Considering the various investigations in which screen tests are indispensable, as, for example, in comparing the grinding capacities of machines, in controlling concentrator feeds, or in investigating and regulating the fineness of pulps in cyaniding and other wet processes, it is certain that the standardization of screen tests is a matter of some importance.

Method of Investigation

The investigation of screen tests naturally divides itself into two parts: (1) a consideration of the size of wire and aperture in the screen used; (2) a study of the actual method of making the tests after the proper screens have been selected. The first branch has received considerable attention of late, but the second has not been discussed at any great length in the technical press, and therefore it is hoped that the following suggestions may be found to have some slight value.

In the common method of making screen tests, the manner of procedure is about as follows: the pulp is dried and weighed; it is then passed through the coarsest screen of the series, very little precaution being taken against dusting, and the operation ceasing when a casual glance seems to show that no more sand is coming through; the material remaining on the screen is removed and weighed, and the material passing through it put through the next finer screen, and so on through the series, all the dust and finest ore being carried through the entire process. Sometimes a washer is placed in the screen to expedite matters. When the screening is completed, the sum of the various weights is checked against the original dry pulp weight. In this process two factors are undetermined: the loss by dusting of the different screens, and the absorption of the moisture by the fine dust, which is not lost. There is another and oftentimes more serious error in the operator's judgment of the time re-

quired to thoroughly screen the sand. The use of a washer is, of course, inadmissible in any careful work.

Proposed Standard Method

The method proposed is as follows: Dry and weigh the pulp, then immediately wet it again and pass it through the finest screen of the series required. This may be accomplished by allowing a small and slow flowing stream of clear water from the tap to fall on the screen, while shaking the screen gently and feeding the pulp slowly near the stream. On the first trial of this method with a 200-mesh screen, the operator will probably clog his screen, but with a little practice he will learn to use the stream of water to keep the bottom clear and will be able to pass fine pulp through a fine screen without splashing or clogging. Now dry the remaining sand and also the screen. Screen the dry pulp again through the same screen, adopting a regular motion, and screening for a definite period of time. This period of time may be ascertained by experiment, screening until no particles of sand show on a piece of white paper placed underneath the screen.

The time required on the finer screens when 500 grams of dry pulp is taken originally, is from 8 to 15 minutes for each screen. It is sometimes said that there is a grinding action in the screen, and that therefore screening should not be too long continued. This may be true for very soft ores, but with ordinary silicious ores the error is negligible, it being impossible after a certain period of time to get enough material through in several minutes of continued screening to make any impression on an analytical balance. In the case of very soft ores the grinding action will be approximately the same with similar ore in the same length of time, and therefore while there would be an error in the absolute quantity passing the screen, the value of the test for comparative purposes would be unimpaired and greater than in the ordinary procedure, where the time of screening and therefore of grinding action is indeterminate.

The pulp remaining on the screen is now weighed, and the difference between this weight and that of the original pulp gives the weight of material passing through the finest screen, or—in milling parlance—the slime. The dust has now been thoroughly eliminated and credited in its proper place without loss, and the remainder of the operation may be conducted dry, going from the finer screens to the coarser or vice versa at the operator's pleasure, but shaking each screen for the definite ascertained time. If the bulk of the material is very fine it is better to go from fine to coarse, because the weight of material to be screened is more rapidly reduced.

In cases where fine pulp is tested and great accuracy

is not required, as in the daily control of tube-mills and classifiers in the cyanide plant, the preliminary drying is not necessary, the weight of the pulp being ascertained by the specific gravity method. The fine screen should not be used until worn out, but should be discarded after about 100 determinations because the repeated oxidations and scourings wear the wire and enlarge the aperture.

The work of screening in this method is likely to prove burdensome when many tests are to be made,

and it will be convenient to fit up a small shaking frame in which the screens may be set, connecting it with the laboratory power-shaft. This also gives the advantage of a steadier and more uniform shaking motion.

I have used and tested this method in mill control work for three years and have found it to give much closer checks than the ordinary method. It may be added that no method of wet screening alone is accurate, though such a method may undoubtedly have its value in approximating mill conditions.

Geological Sketch of the Property of the Hayden Gold Mines, Ltd.

By W. S. DOBBS

The property owned by the Hayden Gold Mines Ltd. consists of three claims partly in Deloro and partly in Ogden townships, Porcupine mining division, Ontario, Canada. These claims are about three and a half miles south of Timmins, Ontario, and can be reached by wagon road from that place. The three claims take in almost all of a rocky ridge which here rises about a hundred feet or so above the surrounding sand plain and muskeg. As these claims have been burned over at least twice, there is no green timber of any sort. In fact, all of claim No. 939 and the greater part of No. 938 have been cleaned bare of all vegetation, thus affording a splendid chance to study the various rocks on this group. Claim 937, on the other hand, especially the eastern portion, is covered by a burden of boulders and drift, glacial and otherwise, to known depths of 10 to 15 ft. in places.

THE PORCUPINE DISTRICT.

The oldest rock is an altered amygdaloidal basalt, called for convenience 'greenstone,' a member of the Keewatin igneous complex. The amygdules are filled with calcite, dolomite, and certain ferromagnesian minerals which have been re-deposited in stringers and veinlets where the shearing and metasomatic action have been pronounced in the schist. This rock (greenstone) along a certain well defined direction and over a considerable area has been subjected to considerable stress and shearing, which has developed a series of channels of passage for the solutions which have precipitated the minerals now found in the shear zone. At least two intrusions have occurred in the greenstone,

and these have exerted tremendous influences on the shear zone and the resulting mineralization and impregnation thereof. The Keewatin greenstone has been intruded first by a granoporphry, which is a quartz or a feldspar porphyry, according to the order in which the various silicates segregated and crystallized in the molten magma. This magmatic intrusion has exerted the most profound influence on the mineralized zone. Secondly, the greenstone has been intruded by a basic distinctly crystalline rock which has been classified by the geologists of the Bureau of Mines as an olivine diabase of post-Huronian origin. In form it is more nearly the dike than the laccolith. This dike has metamorphosed the greenstone, though to a much lesser degree than has the granite porphyry. It is chiefly interesting here as affording an excellent example of the way in which a molten magma erodes, corrodes, and absorbs the adjacent rock in proportion to the distance from the intrusion. Several small barite veins have been found in the zone of metamorphism of the diabase intrusion and these contain from two to six ounces of silver. The veins vary from 2 to 15 inches in width and are about 400 or 500 ft. in length. This diabase dike runs in a southeast by east direction. On claim 937 it cuts the shear zone of schist, which is one of the salient points of evidence to show that the diabase is younger than the porphyry. Nowhere in the vicinity have I been able to find the porphyry and diabase adjacent or in contact, though all known facts point to the existence of such a contact near the southeast corner of 937.

The granite-porphry intrusion probably came from the southwest, and it can be traced the entire length of the three claims. The porphyry appears as an island on the west claim wherever the contact is visible. In various places near the contact is a series of small quartz veins, from a few inches to three or four feet in width, which are apparently the result of the segregation in the molten magma referred to above. The quartz veins along the contact are connected with a series of lateral stringers in the porphyry, and the edges of these veins gradually merge

into the porphyry itself. The zone of mineralization lies roughly parallel to the porphyritic intrusion and ranges in width from 100 ft. in the extreme east to several hundred feet in the west. This possible ore-body and mineral zone has been traced across this entire group into the McDonald claim, southeast of 937. This zone consists of schist very much sheared and partly impregnated with copper and iron pyrite, with a little galena and blende, and is interspersed with and cut by numerous quartz stringers and veins ranging all the way from a fraction of an inch to the big quartz vein lying near the south edge of the zone of mineralization. I have noticed several veins in the shear zone which were three feet and upward in width. Parallel to the contact and within 50 ft. of it lies the large quartz vein, 10 to 50 ft. in width, rising dome-like in place and traced for over 2000 ft. The quartz shows the result of shearing; and the fracture planes are filled with fine black mineral, possibly tourmaline or siderite.

The shear zone was formed as a result of the magmatic intrusion of the granoporphry. The large quartz veins and larger stringers were apparently formed during the period of metasomatic action, as we find copper and ore pyrite in well formed crystals as a result of this intrusion. Thanks to the prospectors' eager desire to stake and sample the porphyries in this district, fairly accurate data with respect to the precious metals contained in the porphyry are available. The porphyry contains from 90c. to \$3.40 per ton in gold. In my opinion it is the 'mother-rock' of the gold. When the post-Huronian diabase intrusion came, the shear zone and porphyry were subjected to further shearing, fracturing, and metamorphism. As a result of this metamorphism gold has migrated out of the porphyry into the fracture planes in the shear zone, which provided a series of channels for the mineral-bearing solutions. In support of this, free gold almost always occurs in the secondary quartz, although two or three instances have been known of its occurrence in the schist out of contact with the quartz.

The larger quartz veins show evidences of shearing and fracture, and minerals have been deposited in the fracture planes, notably siderite, tourmaline, and possibly hornblende. Siderite has been found in the barite veins and in the quartz stringers near the diabase. Galena in places, iron pyrite, and pyrrhotite in a fine state of division have been deposited contemporaneously with the secondary quartz. Free gold and good ore have been found along certain well defined zones, but not in the large quartz veins. Judging by the surface, this vein is very low grade, averaging about \$1 per ton.

The best and most uniform ore has been found where the quartz and schist are very much intermingled, and also where the sulphides are in a fine state of division. My reasons for stating that the porphyry is the 'mother-rock' of the gold are that the porphyry generally

contains small amounts of gold and that the zones of higher gold content are found in those parts of the shear zone which are nearer to the porphyry than to the diabase. The small amount of work done has produced very interesting results and the development work will, I am sure, produce results well worthy of attention from a purely scientific point of view.

Gold Recovery From Mint Residue

By HAROLD FRENCH

During each year, the San Francisco Mint receives up to 2,400,000 fine ounces of gold for refining and minting. From these operations there is collected thousands of worn-out crucibles and corroded furnace

IN THE TOP PICTURE IS SHOWN THE VARIETY OF MATERIAL COLLECTED; AND IN THE LOWER ONE IS THE MILL, SLUICIBOX, AND TAILING DEAMS.

bricks, a large quantity of slag, ash, and sweepings. These products are taken to the treatment plant in the basement of the building. Most of the sweepings are panned first. Combustible materials are reduced by burning as much as possible. Soot from the stacks is rich in gold, and they are periodically cleaned.

For reducing the various materials to be treated, bricks and crucibles are broken by hammers and then

fed into an Elspass mill. This consists of a horizontal die pan seven feet diameter, on which rests four vertical rolls four feet high, and weighing about 1600 lb. These are adjusted by strong springs in accordance with the material milled. A 20-hp. motor causes the die pan to revolve, and the rolls start working at the same time. Water is fed into the mill and stationary steel plows in the middle feed the coarse material under the rolls and divert the pulp against the 40-mesh screens at the side of the mill. The fine material flows into a Pierce amalgamator, then through a 12-ft. sluice-box with burlap-lined riffles to a tailing sump. When the feed contains coarse metal, mercury is seldom used in the mill, as the plows concentrate it near the centre of the die pan, and from 80 to 85% of the gold is recovered in this way. When mercury is added, an extraction of 90 to 95% is obtained in the mill and amalgam traps. The tailing is dried by steam in a pipe under the last settling pan, shoveled into sacks containing 90 lb. net each, assayed, and sold to the Selby Smelting & Lead Co. The tailing averages about 12½¢. per pound. Together with the gold from 'rotting iron,' the yearly output is worth from \$100,000 to \$125,000, from about 50 tons of mint by-products.

Whistle Signals*

1. Steam-shovel engineers must be conversant with all warning signals, and it is made the responsibility and duty of each engineer to give warning of all blasting in the vicinity of his steam-shovel.
2. Sound of the whistle must be distinct, with intensity and duration proportionate to the distance signal is to be conveyed.
3. Each shovel must be equipped with a distinctive toned steam whistle. All shovels are numbered plainly, with a number in full view from all parts of the workings. Employees must familiarize themselves with the distinguishing sound of the different shovel whistles in order that they may readily locate blasting operations and be prepared to safeguard themselves from possible danger of flying rock and debris.
4. Powdermen and blasters must not 'spit' or light a fuse or fire a charge until after the alarm and warning signal has been sounded by the shovel engineer.
5. Signal for blasting shall be a series or succession of short, sharp, quick blasts of whistles, continued for brief period, to be followed immediately by as many long sounds of whistle as there are shots to be fired. To illustrate: if there are 10 shots to be fired, the nearest shovel will sound the alarm series of short, quick 'toots' of the whistle, followed after a brief interval by 10 long sounds, indicating 10 rounds or shots to be exploded.

6. The signals prescribed and herewith set out are illustrated by the word 'short' for short sounds, and the word 'long' for long sounds or blasts of the whistle:

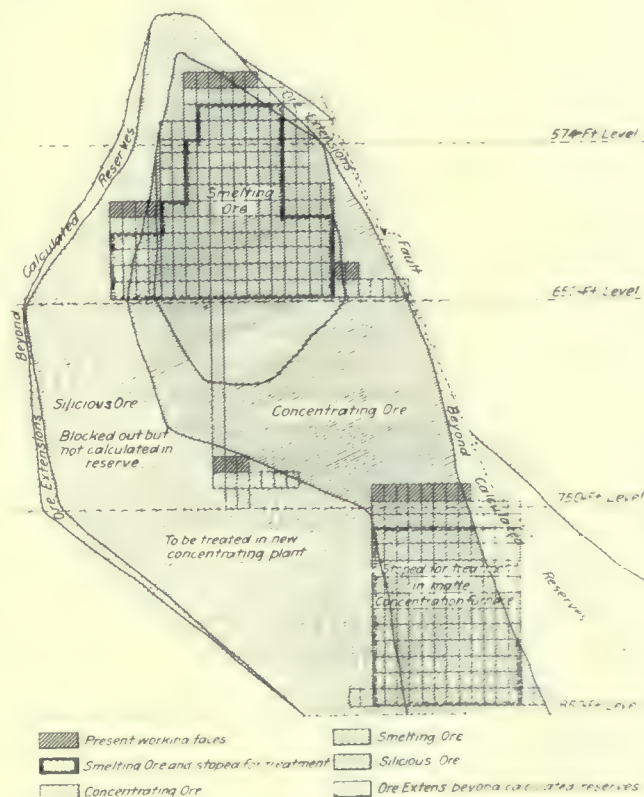

*From the book of 'Rules and Regulations' of the Nevada Consolidated Copper Company.

| SOUND. | INDICATION OF WARNING. |
|-----------------------------|--|
| 1 long, 1 short | Beginning and end of shift. |
| 2 short | Move up shovel. |
| 3 short | Calls waterman, pipemen, and lighters. |
| 4 short | Calls powderman. |
| 5 short | Calls foreman. |
| Series short, quick..... | Warning signal—blasting. |
| Followed by number of long. | Indicates number of shots to be fired. |
| 2 long | Round or charge of blasting completed. |

The signal for 'seam' shots, distinguished from bore-hole shots, top blasting, or bull-doing, will be the regular alarm signal followed by whistle sound of longer duration than the long signal indicating number of shots to be fired. While a seam shot may not be more dangerous than other blasting, the shattering effect of such a shot may cause the throwing of small pieces or particles of rock a greater distance than a top blast would. Employees are, therefore, urged to heed this signal and to seek shelter with all possible dispatch.

The Mt. Morgan Orebody

The origin of this gold and copper producing deposit has been frequently discussed. In the last half-yearly report of the general manager, B. Magnus, are some

notes on its present condition. Ore reserves are as follows:

| | |
|---------------------------|-----------|
| High grade, tons | 1,285,000 |
| Medium grade, tons | 1,960,000 |
| Concentrating, tons | 3,000,000 |

The ore smelted from the mine during the period was 123,247 tons averaging 3.125% copper and 8.516

oz. gold per ton. The Mt. Morgan orebody is one which contains higher metal contents in the centre, surrounding which is ore lower in metals but higher in silica. This lower-grade ore is to be treated in the concentrating mill now being erected. To prepare these blocks of concentrating ore for mining, it is necessary to drive drifts, cross-cuts, winzes, and opening out stope sets through them. Some of this ore is first-class smelting ore. All the ore produced from these workings, with the exception of that which goes to the experimental concentrating plant, is at present being smelted, as, to store it until the permanent concentrator is working, would oxidize it too much to handle in the flotation plant. Further quantities of concentrating ore were also mined in raising to reach the copper ore; this also had to be smelted. In addition to this, a certain amount of ore, outside of the reserves, had to be mined in the course of the usual work, and also had to be smelted. The smelting of this low-grade ore, high in silica, not alone materially increases the cost due to the extra flux necessary, but the low copper content of this silicious ore materially reduces the copper output.

The plan of the 750-ft. level, and a section through one part of it, accompanying the report, shows why the Company had to handle during the period both concentrating ore and silicious ore outside the reserves. While the section herewith reproduced is of only one part of the mine, it is fairly representative. It will be noticed that immediately below the 650-ft. level there is a large block of first-grade smelting ore. The most economical method of mining this, and the one adopted, is to sink the winze from the 650 to the 750-ft. level, then stope up in the usual way. This, of course, as will be seen on reference to the section, involves breaking a considerable quantity of concentrating ore, also some outside the reserves before the first-grade smelting ore is reached. Consideration was given to starting work at the bottom of the first-grade smelting ore. Due to the attending disadvantages this course was not followed, as it would have necessitated cutting double sills, picking up double bottoms, handling some of the ore twice in the top lift, and possibly twice filling in the lower lift. On floor 14, above the 650-ft. level, it will be noticed that stoping has got into the concentrating ore. If this ore was left until the concentrator was running, it would either be lost or could only be regained at considerable cost. For similar reasons stoping outside the first-grade smelting ore on the 650-ft. level is being done.

Rutile production in 1913 amounted to 305 tons, containing 94 to 96% of titanium dioxide. This came from the American Rutile Co.'s property in Nelson county, Virginia. The plant consists of a 10-stamp mill, concentrators, and Wetherell magnetic separator.

The American rotary drilling system for oil wells is being introduced to the Caucasus fields, Russia.

Gold Output of Bendigo in 1913

This old mining district of Victoria, Australia, has produced approximately 19,000,000 oz. gold since 1851. During the past year the output from the dividend-paying mines was 266,942 tons, yielding 104,445 oz. gold and £136,081 in dividends. Assessments totaled £100,152, leaving a net profit of £35,928. The output of the whole district in 1913 was 168,172 oz. Details of the producers are as follows, according to the *Australian Mining Standard*:

| Mines. | Tons. | Ounces. | Divi- dends. | Per. share. |
|---------------------------------------|----------------|---------------|-----------------|----------------|
| Central Red, White & Blue. | 28,232 | 14,626 | £38,400 | \$5.36 |
| Golden Pyke | 13,909 | 10,649 | 23,415 | 4.08 |
| Carlisle | 21,564 | 7,076 | 12,565 | 1.68 |
| Great Northern | 9,830 | 4,989 | 9,750 | 1.56 |
| South New Moon..... | 18,631 | 5,869 | 9,600 | 1.44 |
| Virginia | 19,265 | 6,420 | 8,775 | 1.56 |
| North Bendigo | 9,813 | 3,969 | 7,200 | 1.44 |
| Ironbark | 14,715 | 6,355 | 4,959 | 0.96 |

Mining was interfered with for several months by a number of men striking, as they agreed not to work with non-union men.

Operating Time in the Klondike

The Canadian Klondyke Mining Co.'s manager, J. W. Boyle, gives the following information regarding the 1913 season:

Canadian No. 2 dredge started operations on March 30, has been digging 268 days, has operated over 92% of the time, and has dredged over 2,400,000 cubic yards. Canadian No. 3 started its first operations on May 10, worked 210 days, closed down December 6, operated 89% of the time, and dredged over 1,850,000 cubic yards. Canadian No. 4 started its first operations on May 20, worked 234 days, closed down December 20, operated 88% of elapsed time, and dredged 1,900,000 cubic yards. This gives a total for the three dredges of nearly 6,000,000 cubic yards.

Ore reserves in the Braden mine, Chile, are estimated at 78,000,000 tons of copper ore.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—Students of the geology and mineralogy of the Rand will no doubt have followed Mr. Horwood's articles with great interest, and will agree with me in according him great credit for his patient and laborious investigations in a field that presents many complicated and interesting problems, but it is doubtful whether even the enormous amount of evidence he has succeeded in marshaling will be sufficient to convert those opposed to his theory regarding the origin of the bold contents of the banket beds, when they find that his geological deductions are by no means in accordance with the evidence of the rocks themselves.

Mr. Horwood's description of the causes that led to the formation of the Witwatersrand syncline are as follows¹

"It is, however, significant that the southern and western outcrops (of the syncline) are missing," and "that the contours suggest that the so-called basin really consists of an ancient synclinal valley, formed by the Ventersdorp diabase having broken through, poured over, and flooded the strata of the Witwatersrand beds, which, in consequence of the weight of enormous superimposed masses of volcanic rock and the removal of them from below, sank, dipping inward toward the region whence the material had been withdrawn."

With regard to the first portion of this extract, Mr. Horwood appears completely to ignore the great outcrop of Witwatersrand beds, Ventersdorp diabase, and Pretoria beds that encircle the granite area on the southern side of the Vaal river. These are generally recognized by South African geologists as the opposite outcrop of the Witwatersrand syncline.

The beds in the area are generally vertical and occasionally over-tilted—then dipping toward the granite—and both the Ventersdorp diabase and the overlying Black Reef series, dolomite, and Pretoria beds, encircle the granite so regularly, both in strike and dip, that there is no sign of the unconformity known to exist in other parts of the country, between the Black Reef series and the beds underlying it.

The evidence both on the Witwatersrand and in the Vredefort area points distinctly to great earth-movements, resulting in the formation of a synclinal trough *after* the Ventersdorp diabases had solidified. Consequently, the sinking of the strata, as suggested

by Mr. Horwood, could not have been influenced by the outpouring of volcanic matter, which was a rigid mass when the sinking occurred. This point is further strengthened by the well known fact that the Witwatersrand beds flatten in dip toward the Ventersdorp diabase beds, whereas the reverse would have happened if the volcanic matter had been removed from below them.

Nor will it be generally conceded that "this intense volcanic activity could have also produced numerous lateral fractures." No doubt there are evidences of great fracturing in the Witwatersrand beds, and of the intrusion of many igneous dikes, but they cannot be connected in any way with the Ventersdorp diabase, which is remarkably free from veins or dikes. That the Ventersdorp diabases represent lava flows, which emanated from some source, probably many miles distant from the Witwatersrand, can be assumed from their amygdaloidal character, combined with the vast area over which these flows are known to extend. I have not come across a single instance of a dike emanating from, or connected with, the Ventersdorp diabase, although I have made many investigations at the junction of the igneous and sedimentary beds for the purpose of determining the relationship to each other.

These investigations led me to the conclusion that the lava flows, now forming the Ventersdorp diabases, had passed over a comparatively undisturbed area of sedimentary rocks, which presented no evidence of serious disturbance at the time. This being the case, Mr. Horwood's assumption that the longitudinal dikes so frequently occurring in the Witwatersrand area are connected with the Ventersdorp diabase² cannot be substantiated by any direct evidence of such relationship. Surely there would have been numerous dikes crossing the strike of the beds when such a gigantic volcanic outburst, producing sheets of over 5000 ft. thickness, broke through the sedimentary beds.

Early investigators of the banket came to the conclusion that the beds were tilted into their present position *after* their solidification. Strain phenomena was such a marked feature in every microscopic slide that they could not overlook it. Even the minutest grain of quartzite had been influenced by movement. They, therefore, assumed that the metalliferous contents of the banket beds had been introduced previous to their disturbance and solidification, or conversion into quartzite. Mr. Horwood, on the other hand, assigns the cause principally to the intrusion of basic igneous rocks in the form of dikes.

Fig. 4, on page 567,³ is an illustration of a dike crossing a gold-bearing conglomerate in the Nourse Deep mines. Here it will be seen that the conglomerate bed is cut off sharply against the dike, whereas in the fault, to the left of the dike, the conglomerate is somewhat crumpled. From this evidence it may be

¹*Mining and Scientific Press*, December 27, 1913, p. 1009.

²*Mining and Scientific Press*, October 11, 1913.

³*Mining and Scientific Press*, October 11, 1913, p. 567.

assumed that the dike intersected a rigid bed, whereas the fault may have occurred at some previous period, when the beds were more plastic. In the ascension theory, it is necessary that there were channels of communication between the beds and the source from whence the gold-bearing solutions were derived. Why, then, has Mr. Horwood preferred the dikes that intersected the strata after its solidification, as shown in this illustration, to the pre-existing faults? He has shown conclusively in Fig. 28A, on page 808, and Fig. 28B and 28C, on page 809,⁴ that there is a decided rise in the gold contents as the line of faulting is approached, but he does not show a similar occurrence in the neighborhood of a dike, except in the Crown Reef where an upthrow fault occurred as well.

That basic igneous dikes form channels for the ascension of other than molten mineral matter will not be generally accepted by geologists, and the fact that these dikes contain an infinitesimal quantity of gold, as stated by Mr. Horwood, may be accounted for by their having robbed the gold-bearing beds which they intersected. Metamorphosis by basic dikes has rarely been recorded, and then only in a slight degree. Basic igneous dikes when intersecting coal beds, do not change the nature of the coal for more than a few feet on either side, and in quartzites their influence is almost imperceptible.

Mr. Horwood's comparison between ordinary mineral veins and banket beds (footnote No. 44, on page 604⁵) is certainly far-fetched. On page 723 Mr. Horwood states that in 1905 he came to the conclusion that "traces of gold could be found in every series, and in much of the intervening quartzite, showing that the whole of the Witwatersrand beds had been, to some extent, permeated by mineralizing solutions"; and this is perfectly correct. I have crushed quartzite from the Venterskroon area that yielded 12 dwt. (free gold) per ton, and I have had assays of over an ounce from the silicious beds of the Hospital Hill slate.

Further, my experience goes to prove that gold exists in the Witwatersrand beds where uninfluenced by either dikes or faults, and I have been informed by a geologist of high standing and long South African experience that in the West African mines, now yielding gold from strata identical with the Witwatersrand, there is absolutely no evidence of the existence of igneous intrusions in connection with the gold-bearing conglomerates in that country.

My own investigations have led me to the conclusion that the gold and other mineral-bearing solutions were introduced into the Witwatersrand beds while the latter were in a porous condition, whether by means of fissures or directly from the aqueous solutions in which the beds were formed, as originally proposed by De Launay, is an open question, and, in conclusion, I would ask Mr. Horwood to explain whether every

characteristic of the gold-bearing Witwatersrand beds, which he has taken such pains to collect and describe, could not be equally as readily accounted for if the gold had been derived from other sources than the igneous dikes, granting that time and pressure were given credit for the metamorphism and crystallization of the contents of the conglomerate. Mr. Horwood will no doubt be interested to learn that when the Rietfontein reef was being opened up, a number of nuggets of gold were taken from the mortar-box, and some were found in handling the ore. One of these nuggets weighed over two ounces, and several were over an ounce in weight. There were about 20 in all. They were handed to me for exhibition in the Chamber of Mines' museum, of which I was curator for a number of years, but at the outbreak of the war they were returned to the late Harold Strange, managing director of the Rietfontein company, and they are now probably in the possession of his executors. They were ordinary nuggets such as are found in alluvial gold-bearing deposits.

London, February 18.

DAVID DRAPER.

How Close Can You Estimate Heights?

The Editor:

Sir—The accompanying photos were taken at the Quartette tailing pond during a recent examination at that property. They illustrate an interesting case, where nature shows in a 'laboratory' way the cause and effect of cañon and gorge topography. The miniature gorge illustrated was formed by a very small overflow stream from the tailing pond, which cut quickly

HOW HIGH ARE THESE CLIFFS?

through a series of sand and slime strata which had been previously caked and dried into layers under desert conditions. The walls are about four feet high and the individual layers are fractions of an inch in thickness only. It has been interesting to note various estimates as to the height of the walls on casual inspection of the photos. These have ranged from 20 to 2000 feet.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Moisture in ores from the Rochester Weaver leases, Nevada, averaged 3.6% in 1913.

Copper ore smelted at Mt. Morgan assayed 55.6% silica, at a cost of 13c. per unit to flux the silica.

An endless-rope haulage 2400 ft. long is working satisfactorily on No. 42 level, south of No. 6 shaft, of the Osceola mine, Michigan.

Mine drainage at the Brunswick property, Grass Valley, California, is done by a Dow pump, which is on the lowest level, 1250 ft., and lifts the water to the drainage adit, 128 ft. under the collar of the old incline shaft. Costs have been reduced since its installation.

The danger of killing mosquitoes with the hands has been drawn attention to by the Liverpool School of Tropical Medicine. The mosquitoes are liable to carry parasites which cause *elephantiasis*, so that especial care should be observed in districts where the latter disease is known to exist.

A carat is 1/24th part. The term has been generally adopted to indicate the gold fineness of alloys used for industrial purposes. The carat, or fineness, represents the parts of gold per twenty-four parts. The remainder is generally silver or copper used for hardening and cheapening purposes.

Where a person wilfully trespasses on the patented land of another in Arizona, and digs shafts thereon which may become a pitfall for stock belonging to that other, he is guilty of a misdemeanor under the provision of Section 532 of the Penal Code, and upon complaint properly sworn to before the nearest justice of the peace, can be criminally prosecuted.

Demand for molybdenite is growing, and supplies are irregular, so that at the present time as high as \$1500 per ton has been paid for clean molybdenite. It is possible that better prices could be obtained, unless these high prices call forth a large supply and again depress the market. For a number of years the average price has been about \$500 per ton, but owing to the growing demand and the decrease in supply, the prices indicated above have been reached. This condition will only be permanent if the supply remains limited. From an operator's point of view, it would not be profitable to undertake work unless it was justified by the prices of about \$500 per ton for clean concentrate, in spite of the high prices at present indicated.

Matte from cyanide clean-up is easier to treat when it contains more gold than silver. If it is rich in gold, with some silver, the gold will be reduced at once and the silver remains in the matte, especially when treating it with iron shaving, according to G. Simpson, of the Ketahoen mine, Sumatra. For every 100 oz. of silver in a silver matte he collects, 2.2 lb. of turnings is added in melting. Cast iron is not as good as steel for this purpose. The matte is run down first with 1.1 lb. of iron, then a second time with a similar quantity, it being found better to do this than to melt hot at once. After refining gold and silver bullion in a crucible, it is found that matte sticks hard to it when poured into a mold. The higher the value of the matte, the tighter it adheres to the bullion. If a little cyanide salt is added during melting, this makes the matte of lower value, and it separates easily from the bullion. The addition of a little iron shaving during melting acts in a similar way, is cheaper, and there is no danger from fume.

Treatment at the Grand Junction mill, Waihi, New Zealand, shown in the accompanying cut, is as follows: The ore consists of a gangue of quartz and calcite, with 8 to 10% sulphide, in a country rock of highly altered dacite. Metals average \$8 and \$1 silver per ton. The 40 stamps, having been increased to 60, crush an average of 8400 tons per month, yielding bullion worth about \$80,000. Cyanide solution

GRAND JUNCTION MILL, WAIHI, NEW ZEALAND.

and lead acetate are added to the batteries. The pulp flows to three elevator wheels and then to a series of spitzkasten. The underflow passes to Wilfley tables and the overflow to eight tube-mills, two being 19¼ by 4¾ ft., and the others 16¼ by 4¼ ft., revolving at 27 r.p.m. All the ground pulp goes to thickeners, from which it is pumped to one of a series of 12 flat agitators revolving at 4 r.p.m., which act as storage tanks. It is then pumped to Pachuca tanks for agitation for 18 hours. Filtration is done by a Moore type of plant. All solutions are precipitated on zinc shaving. Melting the fluxed precipitate is done in Ballack tilting furnaces, and the bullion refined in a kerosene-fired furnace. Costs of milling and treatment are about \$1.50 per ton.

TORONTO, CANADA

KIRKLAND LAKE MINES.—NIPISSING PROFITS AND FUTURE.—INTERNATIONAL NICKEL PROFIT SHARING.—BLACK LAKE ASBESTOS CO.—MINERAL RIGHTS ON LANDS IN ALBERTA.

Kirkland Lake flotations are still creating considerable excitement in London, notwithstanding the severe criticism the methods employed by the interested parties have undergone. From the Kirkland Lake Proprietary, the original flotation, which appears to be an outgrowth of the Union and Rhodesian Trust, C. A. Foster, of Haileybury, received £25,000 in cash for which he gave to the Company the benefit of those contracts and negotiations which he had entered into for properties in the Kirkland Lake district. According to the prospectus of the Kirkland Lake Proprietary, after the original issue of 75,000 £1 shares for every two shares issued up to an additional 50,000 shares, Mr. Foster was to receive either £1 in cash or one fully paid-up share of stock. It is understood that upon receipt of this £25,000 in cash, Mr. Foster purchased 25,000 shares of stock, also obtaining, as per the original agreement, an additional 12,500 shares, giving him a total of 37,500 shares, which is the largest individual holding in the Company. Mr. Foster then sold to the Kirkland Lake Proprietary a 99½% interest in the Tough-Oakes mine in Kirkland Lake, in which he is also the largest shareholder. It is understood that the price paid was \$3 per share for the 450,000 shares outstanding. For the purpose of taking over this property, a London company called the Tough-Oakes, Limited, was formed with a capital of £500,000, shares of which were issued at par. When this Company has been successfully launched, Kirkland Lake Proprietary will receive back all the money which it has spent on the property, and in addition 100,000 shares of Tough-Oakes stock. It is understood that the other properties which the Kirkland Lake Proprietary has under option will be handled in a similar manner. Reports on these various properties, the Tough-Oakes, Burnside, Sylvanite, and Teck-Hughes, have been made by H. H. Johnson. These reports leave much to be desired. Mr. Johnson, notwithstanding the fact that the Tough-Oakes mine has only been opened at the 250-ft. level and has a comparatively small amount of driving done, estimates, with insufficient data, developed and prospective ore to the value of £220,000. From this, however, must be deducted the cost of further development and the expenditures necessary to equip the property with a mill and plant. Mr. Johnson further estimates that the annual net earnings will be £150,000 per year. These figures are based on the returns from a mill having a capacity of 30,000 tons per year, and, with only 19,000 tons of ore actually developed, the estimate of annual profits is certainly open to criticism. The necessity for caution by prospective investors in the securities of any of these Companies is evident, and while the properties under consideration have considerable merit, the possibilities are that greater profits will accrue to the promoters than to the stockholders.

The recent activity in the stock of the Nipissing Mining Co., which dropped from about \$9 to \$6.40 per share, is believed to be preliminary to a cut in the dividend. This Company at present is paying dividends at the rate of 30% per year on a capital of \$6,000,000, quarterly dividends being 5% regular and a 2½% bonus. In the event of action being taken, it is believed that the bonus will be dropped. In this connection, a recent circular sent out under the signature of E. P. Earle, president, is of interest. Mr. Earle states that the report for the year 1913 will be sent to the share-

holders in April, and will contain full particulars of operations for the year ended January 31, 1913. Inasmuch as there has been of late a falling off in the net earnings due to the lower average grade of the ore produced, and as it is impossible for the management to state whether this condition will prove temporary or permanent, it was considered advisable to submit a brief statement to the stockholders. The nature of the orebodies in the Cobalt district is such that it is impossible to predict earnings far in advance. The earnings of the Company will in the future, as they have in the past, depend upon the continuation of the known veins which are now being operated and the discovery of new orebodies. There have been periods in the past when earnings have fallen off because of conditions similar to those now existing. The Company owns a large area of undeveloped territory which presumably contains orebodies of value. Mr. Earle states further that during the past three months five new veins have been found in partly developed ground which will aggregate about 8 in. of 2000-oz. ore. On January 1 the Company's ore reserves were practically the same as were estimated for December 31, 1912, when they stood at 9,643,338 oz. The Nipissing, in common with the majority of the Cobalt mines, is depleting its high-grade ore reserves at a faster rate than they are being supplemented by the discovery of new orebodies. The high-grade veins have been responsible for the large dividends paid by Cobalt mines, and, notwithstanding the large tonnage of low-grade ore available, a cut in the dividend is inevitable, as the high-grade ore becomes less. Statements for the last few months showed that the net value of the ore mined varied between \$165,000 and \$185,000 per month. As the present dividend requirements call for \$150,000 per month, and working expenses are between \$50,000 and \$60,000, it is easily seen that unless a decided change for the better takes place, a reduction in the dividend rate is only to be expected.

Of the 3000 shares of International Nickel common stock which employees of the Company were recently permitted to subscribe for at \$110, practically all has been taken up. Of the 4000 persons on the payroll, 40% subscribed for their allotment of shares. The minimum subscription was one share to any employee of under five years' service receiving up to \$825 per year, while the maximum subscription was 10 shares to anyone receiving over \$4000 per year who has been in the employ of the Company for over 10 years. This stock will be paid for in monthly installments, and the employees will receive dividends as soon as the first installment is paid. An additional bonus, equal to 5% of the stock so paid for, will be distributed equally to such employees as retain their stock and remain in the employ of the Company. The success of this innovation, which is the first of its kind among any of the large mining companies in Canada, has been very gratifying to the management.

The statement of the Black Lake Asbestos Co. for 1913 is not likely to prove a very pleasing document to the shareholders, as it shows a loss of \$20,939 on the year's operations. From the available figures, it does not appear that the Company sold any asbestos in 1913, as the only receipts given in the profit and loss statement are \$1617 for rents and \$4796 for interest, against an expenditure of \$27,352. The directors state that the results of the past year's operations have been unfavorable owing to a decline in the percentage of asbestos obtained from the rock, due to a change in formation in one of the largest pits. The asbestos fibre was 3.8% for the last six months of the year, as against 5.1% for the preceding half-year. It is, however, stated that new pits are being opened which will furnish asbestos rock equal in quality to the best now being mined. The Company is in a better financial position than the profit and loss statement would indicate, as it has \$73,000 loaned on col-

lateral security. Current assets, including this loan, amount to \$150,881, while current liabilities, including a bank overdraft of \$23,366, total \$29,616. The entire estimated output of the Company has been contracted for up to next October at advanced prices, and indications are that a still higher price will be obtained for the balance of the output. The Black Lake company was one of the several large consolidations for which a bright future was predicted. On account of the condition of the asbestos market, and exceedingly ill-advised financing on the part of the promoters, the Company was forced into liquidation. After it was reorganized, the capital was decreased and fixed charges largely eliminated; but notwithstanding this, the Company does not seem to be making much headway.

On account of the right of the Dominion Government to grant mineral rights on lands in the vicinity of Calgary being questioned, an interesting situation has arisen in connection with the oil and gas leases in that field. This threatens to lead to a great amount of litigation which may possibly invalidate the securities of those who invested either in oil leases or in the stock of oil companies. It has been generally understood that land filed on for homestead purposes prior to 1889, carried with it the mineral rights, and that all homestead lands taken up since that date were without such rights. In 1889 an order-in-council was passed which provided that, under patents issued by the Crown, all mineral rights should be reserved. This condition prevailed until 1908, when a new act was passed which expressly provided that mineral rights should be excluded from homestead entries. It is on this understanding that leases have been applied for, and during the recent oil excitement in the field southwest of Calgary, about 50% of the leases in the district are for oil and gas rights under lands that were homesteaded between 1890 and 1908. It is now stated on good legal authority that during these years the Government had no right under the law to take these reservations of mineral rights from the homesteaders, and that these rights belong to the owners of the surface rights or to anyone to whom the surface rights may have been assigned. Should this contention be upheld, a large part of the leases recently applied for would be valueless; but on the other hand, it is pointed out that homesteaders who have entered on their lands and ultimately accepted a patent with the knowledge of the regulations supposed to be in force, now have no grounds for complaint.

JOHANNESBURG, TRANSVAAL

ESTIMATE OF THE LIFE OF THE RAND BY THE CHAMBER OF MINES.

— OTHER AREAS LIKELY TO BE PROFITABLE. — PROBABLE DEPTH OF MINING. — RESULTS IN 1913.

A mild sensation has been caused in mining circles by the appearance of a statement, prepared by the Chamber of Mines for the Government Economic Commission, showing the probable life of the Witwatersrand goldfields. The exact length of the life of the Rand was not estimated, because so many factors enter into the question, but the probable life of the Rand as it is known today is, according to the Chamber of Mines, so much shorter than anticipated, that it may not be out of place to give the principal features contained in this official statement. First, it is pointed out that the Rand goldfield has been proved to extend from Randfontein on the west to Holfontein on the east, a distance of over 60 miles. The limit to deep mining throughout this length was taken at 7500 ft. vertical, because the government has actually refused to proclaim any ground for mining purposes where the 'reef' is supposed to exist below that depth. To arrive at the probable gold contents of this deep unproved ground, this has been taken as equal to the gold contained in the last 1000 ft. of the developed reef, no

allowance being made for the flattening or decline in gold content in depth, both of which are known to exist. If working costs continue as at present, the Chamber of Mines estimates that in 42 of the mines, the other mines not included, there are 550,000,000 tons of profitable ore, which, at the present rate of crushing by the 42 mines, will maintain the Rand with only sufficient ore to keep the mills running for about five years. It must be admitted that the method of arriving at this conclusion is only an approximate one; but coming from such an authority as the Transvaal Chamber of Mines, it has attracted considerable attention. It was further estimated by this institution that under existing conditions the tonnage crushed in the year 1920 will probably fall to one-half its present quantity, an estimate which in most quarters seems difficult to believe. The sting contained in the above estimate of the future of the Rand is, however, to some extent removed by subsequent statements, one being to the effect that outside this official estimate there are three properties in the East Rand now in

A SAMPLE BANKET FROM THE NEW RIETFontein.

course of development, comprising 4140 claims and capable of yielding 1,800,000 tons of profitable ore per year, while there are eight other properties closed down in the same neighborhood, owning 6420 claims, whose milling capabilities may be assumed to be 2,500,000 tons per year, not taken into consideration. Then it is pointed out that there are no less than 86,000 other gold claims in the Far East Rand, where boring operations have proved the reef, also excluded from the official estimate; so that it will be seen that the estimate made by the Chamber of Mines is a conservative one. The Kimberley Reef series, and the probable westerly extension of the Main Reef series, are lightly considered; but it seems clear that the Chamber of Mines does not look for much extension in the central and western Rand, the Far East Rand being best able to add to the present gold production of the Witwatersrand.

If this statement of the Rand's future be studied, it will be seen that, while it may be a broad and general statement, there is much in it with which most engineers will agree. At the same time, any attempt to fix the life of the Rand by years must necessarily be an approximate one only, on account of the many varying factors and difficulties surrounding the question. There is, for instance, the question of the limit to deep mining on the Rand which the Mines Department seems to have fixed at 7500 ft. vertical. The present deepest mine on the Rand has attained a depth of over 5000 ft., without adding materially to the cost of working, and on the basis of working costs, an ultimate depth of 7500 ft. vertical seems quite within reach. As for mining difficulties due to depth, these are not particularly noticeable, and with the excellent underground conditions the depth

limit assumed seems attainable. The real difficulty surrounding 'ultra-deep' mining on the Rand seems to be that of the gold content of the reef, because, taking the Rand as a whole, quite one-half of its entire length seems to have depreciated to such an extent as to make the task of deep mining one of working at a profit a reef at a depth of over 5000 ft. yielding only \$5 gold per ton.

This depth has not yet been attained on the western Rand, but it is doubtful whether at such a depth the average value will exceed \$5 or \$6. In the central Rand the prospects of deep mining are good, but it is doubtful whether the output from the western and central Rand will improve in the future, while that from the east Rand can only expect at least to be maintained. The only section of the Rand affording scope for an increased output is that known as the Far East Rand, beyond the town of Boksburg, but this opening for new mines was fully dealt with in the Chamber of Mines statement submitted to the Economic Commission. There can be no doubt, however, that the Rand production of gold has reached a point scarcely likely to be exceeded, and one that only with difficulty will be maintained after the next ten years.

It has been the rule on the Rand for the output of gold to steadily increase, month by month and year by year, for the last 20 years, and to be told by no less an authority than the Chamber of Mines that these increases were coming to an end, came as a shock to the Rand. Last year's figures show, however, that this is the case, for while in 1912 the value of the Transvaal gold output was £38,686,250, the total value of last year's output was only £37,372,952, being the first time since the Rand was discovered that the output of gold registered under normal conditions a decline. [The strike during the past year helped to reduce the output.—EDITOR.] It seems evident that increases in the future will become more difficult, but the present output ought to be maintained for more than five years, and probably when the permanent decline sets in it will be more gradual than the statement made by the Chamber of Mines would lead us to expect.

During 1913 all the mines treated 25,628,432 tons, as against 25,486,361 in 1912. The average yield declined from \$6.96 to \$6.66 per ton, the lowest yet recorded. Costs fell from \$4.48 to \$4.30, and working profit from \$2.40 to \$2.28. Aggregate profits were £12,189,105, as against £12,678,095. There were 9337 stamps and 278 tube-mills working, compared with 9449 and 262, respectively, and the stamp-duty rose from 8.39 to 8.82 tons per day. Sorting fell from 12.57 to 10.74%. Dividends increased from £7,952,994 to £8,194,099.

The output in January 1914 was worth £2,768,470, the lowest for many years. The tonnage treated was 1,902,433, averaging \$6.56 with a profit of \$2.22 per ton.

LONDON

THE INSTITUTION OF PETROLEUM TECHNOLOGISTS INAUGURAL MEETING.—FLOTATION LITIGATION, ELMORES V. THE SULPHIDE CORPORATION DECISION.

It is not only the engineer interested in metalliferous mining who finds it expedient to have a professional society to protect the public against impostors. Those connected with petroleum have also been stirred to form such a society. I recently attended the inaugural meeting of the Institution of Petroleum Technologists, and, to judge by the large attendance and the character of the men present, the new society appears to have a destiny. Sir Boverton Redwood is the first president, and supporting him on the platform were such well known men as Vivian Lewes, Sir Thomas Holland, Cunningham Craig, and John Cadman. The president made a statement formulating the aims and objects of the Institution. The commercial element does not come within its scope. There is no desire to push the advantages of petroleum and

its products in their applications as producers of power and light or as lubricants. The sole aim is to advance the scientific treatment of petroleum problems in their geological, chemical, and mining aspects, and to promote the better training of the future leaders of the petroleum industry. After Sir Boverton's inaugural statement, three short addresses were delivered by Sir Thomas Holland, Cunningham Craig, and Vivian Lewes, the first being strictly technological, and the other two being in the nature of amplifications of the presidential address. Sir Thomas Holland's lecture was devoted to the geometry of the various types of asymmetrical anticlines, and gave mathematical directions for tapping the crests of the successive oil-bearing beds. In his address, Cunningham Craig said that the public and the financiers had to be taught the elements of petroleum geology, and petroleum mining must be put on a strictly business footing. Mr. Craig has already earned the thanks of his professional friends by his refusal to be talked into giving favorable reports either by governments or promoters. In this connection, his views on the chances of finding oil in South Africa are well known. He is the author of that excellent book, 'Oil Finding.' He was also eloquent on the lack of opportunities in England for specialized training in connection with petroleum, and he commended the action of John Cadman, professor of mining in the University of Birmingham, for his enterprise in establishing a course where geology, chemistry, and mining are taught from the point of view of the petroleum technologist. By means of this school, it is hoped that native talent will be trained, fitted for the multitude of posts now offered. At the present time, chemical advice is sought on the Continent, and engineers and drillers are brought from America or Galicia. The concluding address, by Vivian Lewes, called attention to the chemical side of the subject, as affording the possibility of even greater prizes than the geology and engineering. The removal of troublesome sulphur compounds affords an important field for research, and the production of petrol products from petroleum by cracking or otherwise is an equally attractive subject.

Three weeks ago I gave particulars of the hearing of the appeal from the New South Wales court, by the Judicial Committee of the Privy Council, in connection with the suit by the Elmores against the Sulphide Corporation, alleging that the Minerals Separation process as used by the Corporation was an infringement of the Elmore patent of 1901, which claims the use of acid for aiding the selective action of oil for metallic or sulphide particles. The five judges appeared to be inclined to restrict the arguments to this narrow scope, and for that reason there was a general impression here that the Elmores would win. It comes as a surprise, therefore, to find that the judgment sustains the Australian court and dismisses the appeal, leaving Minerals Separation the victor. Unfortunately, the practice of the Judicial Committee does not indicate whether the judges are unanimous. In the purely English courts each judge delivers his individual opinion. It is probable that the five were divided and that the majority was a case of three to two. Though the arguments before the court appeared to be in favor of narrowing the issue to the 1901 claim, the judgment rambled over much wider ground, and finally the judges said that Elmore used oil as the concentration and flotation agent, while Minerals Separation depended for the same effect on the principle of surface tension. The case was presented differently by the Elmores in this litigation on the New South Wales patent from the form in which the lawsuit was fought in England. In the earlier case both patents, that for oil in 1898, and that for acid in 1901, were cited. As all the judges pronounced against the 1898 patent, the Elmores decided to rely solely on the 1901 patent in the New South Wales case. On the other side, the defenders of Minerals Separation were, in the interval between the House of Lords and Judicial Committee hearings, placed in a more favorable position by the

consolidation of interests with the De Bavay company which owns the Potter patents. In the old days, Minerals Separation was 'between the devil and the deep sea,' being attacked by oil on one side and buoyant bubbles on the other. When peace was made with bubbles, greater stress could be laid on the surface tension principle, and the oil could be relegated to a more obscure position. This presentation of the surface tension proposition appears to have formed the basis of the Judicial Committee's decision. The flotation question bristles with so many details and apparent contradictions that it is well nigh impossible to arrive at any concise view. Moreover, the whole of the facts are not known to the public and to journalists, so it is easy for us outsiders to fall into error. I may be committing an egregious blunder, therefore, in wondering why the Elmore vacuum patent was not cited in the case. It indicates the use of surface tension and small amounts of oil and acid, and it antedated by a year the main Minerals Separation patent of 1905. Probably the reason is that the vacuum process runs against the Potter surface-tension process patented in 1902, and this was the enemy's territory by purchase.

NEW YORK

COPPER EXPORTS AND TRADE IN EUROPE.—FEDERAL MINING & SMELTING CO.'S SMELTING CONTRACT.—CALUMET & ARIZONA MINING CO.'S REPORT.—MEXICAN NOTES.

Curiosity as to how exports of copper to Europe can continue at record-breaking figures in spite of dullness in business there as well as in this country, seems to be becoming more general. From 1909 to 1912 exports increased yearly at the rate of about 6% per year, but during 1912 there was a slight decrease. But the 1913 exports increased nearly 40% over the preceding year, while the exports of the past four months have averaged nearly 10% larger than during 1913. Exports in February were 83,899,183 lb., and are estimated at 85,000,000 lb. in March. C. W. Morse, who has just returned from Europe, has made the following statement: "I was impressed with the general falling off in business, which at this particular time is more than normal. In Germany, France, and England every line of business is showing a marked decrease." In putting these two facts side by side, the state of mind of the copper consumer can be best shown by a large question mark. Following the Democratic victory in 1912, and the knowledge that the tariff would certainly be reduced, high exports of copper to European manufacturers were perfectly natural last year. The copper consumed during the Balkan war helped out through the necessity of restocking arsenals with ammunition; but what basis exists for the present unprecedented flood of copper to Europe is hard to see.

The suit of the minority stockholders of the Federal Mining & Smelting Co. to annul its smelting contract with the American Smelting & Refining Co. is now being heard, and the facts brought out make interesting reading for everyone. It will be remembered that, in 1905, Charles Sweeny sold the control of the Federal, held by himself, J. D. Rockefeller, and George J. Gould, to the Guggenheim organization. Guggenheim representatives went on the Federal board, and the smelting contract with the American Smelting & Refining Co. was extended for 25 years. It soon developed that the ore reserves in the Federal were not nearly so rich as supposed. Meanwhile a change in the smelting situation caused an unexpected marked decrease in the smelting charges on the ores of the district. As a result, the Federal was soon making almost no profit out of mining its ores, while the American Smelting & Refining Co. was making a good profit at smelting them at a rate much above the prevailing one for competitive ores. This state of affairs has been worrying the minority shareholders, and they are trying to break the smelting contract. A contract is a contract, however, and,

unless not entered into in good faith, usually has to stand even if it proves a losing one.

The Calumet & Arizona Mining Co., which operates mines and a smelter in Cochise county, Arizona, has published its report for 1913, containing the following information: Development covered 15,635 ft. at the Irish Mag, Oliver, and Powell shafts of the C. & A. mine. Little work is being done at the first-named just now. No new orebodies were opened in the Oliver, but a good tonnage of ore from small shoots at 1150 and 1250 ft. was mined. This area has several small rich sulphide shoots. A large reserve was developed between the 1250 and 1350-ft. levels. Prospecting is under way at the Powell shaft. At the Courtland mine, development totaled 3591 ft. Until November 30, ore shipments averaged 600 tons per week. In July, the Germania shaft started to move and prevented hoisting ore. By arrangements with the Leadville Mining Co., its Maid shaft was used for this purpose. The mine is now leased. These two properties produced 135,979 tons of ore averaging 4.93 and 5.40% copper.

At the Superior & Pittsburg mine the total work was 47,201 ft., at the Hoatson, Junction, Briggs, and Cole shafts. Results to 1000 ft. in oxidized ore at the Cole have been satisfactory. The Junction shaft was concreted, being finished on February 8, 1914. At 1300 ft. south from the shaft, ore was opened nearly to the 1200-ft. level. Along the Copper Queen side-line a fair-sized body of good sulphide ore was opened. At 1400 ft., in the southwest corner of the Ormond claim, a shoot 40 ft. wide and 60 ft. long was developed. Steady shipments were made from 1300 ft. at the Briggs area. The shaft was sunk to the 1500-ft. level of the Junction. A motor line at 1400 ft. will haul Briggs ore to the Junction. Considerable ore was opened at the Hoatson shaft down to 1400 ft. Ore mined totaled 393,941 tons, averaging 6.27% copper. Shipments to the smelter were 376,452 tons. The new smelter is in full operation. It cost \$2,218,218. Total earnings from copper, gold, and silver were \$9,160,975, and sundry revenue, \$21,020. The net income was \$1,074,637. Expenses on outside properties were \$146,830, covering work at the Daggs-Newman and Copper Giant claims in Pinal county, and the Amole and New Cornelia in Pima county, the latter at Ajo. Work at the latter has been the proving of ore reserves, water development, and surveying a railway from Ajo to Tucson. Estimates of the ore are as follows: available by steam-shovel, carbonate ore, 11,954,400 tons averaging 1.54% copper; sulphide ore, 20,526,800 tons averaging 1.54%; underground mining, sulphide ore, 7,776,800 tons averaging 1.40%; and rock stripping, 3,308,400 tons containing 0.60% copper. The carbonate ore will be leached, and a good recovery by flotation of the sulphide ore is shown by tests.

Work is to be resumed by the Amajac Mines Co., whose property is in the state of Jalisco, Mexico. A 50-ton mill is in course of construction. Walter J. Pentland is general manager. Nearly 300 tons of ore per day is being treated in the new Cinco Minas mill. The recovery is up to 96%. The Company is marketing its bullion through the Sociedad Afincadora de Metales, the French refining concern of Mexico City. Arrangements for the marketing of the concentrate have not yet been closed, but these products probably will be shipped to Wales. Mine development has been resumed and plans have been made for extensive work. The main working shaft is to be sunk to a depth of 1000 feet.

From the Amparo Mining Co., 150 tons of concentrate has been sent to the Selby smelter in California. The average value is \$500 per ton. This is the second shipment to this smelter. Much interest has been attracted locally by an interview with Emeterio de la Garza, published in the *Sun*. Sr. Garza has served under Diaz, de la Barra, Madero, and Huerta, having been the confidential envoy of the last at Washington. He advocates a peace conference.

General Mining News

ALASKA

The annual report of J. R. Willis, collector of customs for the territory, at Juneau, shows the following results for 1913:

| | |
|--|--------------|
| Total commerce, domestic and foreign..... | \$67,422,307 |
| Decrease compared with 1912, due to lower gold yield | 5,318,753 |
| Gold and silver exports to United States..... | 12,959,266 |
| Copper ore and matte | 3,765,132 |
| Tin ore and concentrate | 72,734 |
| All fish products | 15,803,073 |
| Gypsum | 129,375 |
| Marble | 92,588 |
| Shipping, foreign and domestic, total, tons..... | 1,389,306 |
| Population, decrease | 1,126 |

CORDOVA

Heavy snowstorms have interrupted traffic on the Copper River railroad, and trains have been stalled.

FAIRBANKS

It is proposed to hold an exposition here in 1917, to commemorate the fiftieth anniversary of the acquisition of Alaska by the United States from Russia, and the probable completion of the authorized railroads from one of the southeastern ports to Fairbanks. A company with 15 directors and a capital of \$1,000,000 is to be formed.

JUNEAU

The 1913 returns of the mines was as follows:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United. Ready Bullion. | 700-Ft. Claim. |
|-------------------|--------------------|----------------------|----------------------------------|-------------------|
| Tons | 227,112 | 886,057 | 222,992 | 225,435 |
| Gold output | \$489,697 | \$2,358,422 | \$511,391 | \$532,152 |
| Profit | 171,797 | 1,223,437 | 323,602 | 325,669 |
| Dividends | 180,000 | 1,000,000 | \$414,460 | |

ARIZONA

According to official statements at Globe, Gila county, the Tucson, Phoenix & Tidewater is to be constructed from Tucson, in Pima county to Phoenix in Maricopa county. The line will be 120 miles long and will probably run through Florence in Pinal county.

COCHISE COUNTY

The Shattuck-Arizona company paid 50c. per share on April 20, amounting to \$175,000, and \$1,925,000 to date.

GILA COUNTY

It is probable that an electric tramway will be constructed to operate between Globe and Miami.

Shipments of ore from the London-Arizona Consolidated Copper Co.'s mines to the smelter are now proceeding regularly. A recent shipment of 50 tons averaged 6.2% copper and 3 oz. silver per ton. The net smelter returns on this carload were \$414. Four more cars are now in transit.

SANTA CRUZ COUNTY

Smelter returns from ore sent from the Patagonia Mining & Development mine, gave 30 oz. silver and 13.72% copper, the net value being \$46.28 per ton.

CALIFORNIA

Oil statistics for February are as follows: Rigs completed during month, 17; wells drilling, 225; wells completed, 44; wells abandoned, 23; producing wells, 5787; net output, 7,943,638 bbl.; shipments, 7,384,406 bbl.; and stocks, 51,180,067 barrels.

AMADOR COUNTY

Dividends paid by the South Eureka, Bunker Hill, and Fremont companies during the first three months of 1914 are \$62,997, \$15,000, and \$12,000 respectively. The Ione Coal & Iron Co. has received an offer for the output of its coal mine at Ione. The Central Eureka mill is again in operation. The Plymouth Consolidated Gold Mines, Limited, has a capital of 240,000 £1 shares, of which 127,000 are issued fully paid, and 113,000 were offered to the public at par on January 26 to 28, 1914, according to the prospectus. These shares were over subscribed for in short time. The directors are John Barry, David Richards, and Cyril Wanklyn, all on the board of the Sons of Gwalia, Limited, operating a profitable mine in Western Australia. Ore reserves in the Plymouth are 110,113 tons worth £150,667, with a profit of £72,858. Working costs will be about \$2.72 per ton, and 90% recovery is allowed for. A 300-ton mill is now being erected, and should be working in September next.

BUTTE COUNTY

During 1913, the Oro Water Light & Power Co.'s dredges recovered gold worth \$542,240, at a cost of \$255,538, and with a net return of \$275,579. Profits of the whole concern were \$349,455.

Five dredgemen have gone, and nine others are leaving Oroville for Dawson, Yukon, where they will be employed by the Guggenheim company. Fire destroyed property valued at \$100,000 at Oroville on March 19. Two boats of the Oroville Dredging Co. recovered \$4791 during the first week in February.

IMPERIAL COUNTY

(Special Correspondence.)—The Imperial Reduction Co.'s mill and cyanide plant is now in its second month, with good results. It consists of three Gates dry-crushing rolls, three 8-ft. Hardinge tube-mills, fifteen Deister tables, one Dorr thickener, two Trent agitators followed by two Trent replacers. The ore reserves are extensive and of a profitable grade.

Ogilby, March 13.

NEVADA COUNTY

It is reported that San Francisco people have acquired the Golden Gate mine, a promising property near Grass Valley. Three men had their right hands injured in various ways at the Champion mine. At the Empire 3800-ft. level, W. Allen, an old Grass Valley miner, was killed by a descending skip, through some unaccountable cause. On May 13, 1913, Guiseppe Domiano fell down a chute in the Birchville mine. He is now suing for \$31,247.50. Five claims in the Meadow Lake district are in dispute as to ownership.

PLACER COUNTY

C. H. Dunton, collector of minerals for the Sacramento Valley Expositions Commission, has been making inquiries in this county for samples of gold, copper, asbestos ores, and clay and marble. Several men were injured on March 20, by a gravel bank at the Goggin placer mine, forty miles from Forest Hill, caving on one and the nozzle striking others.

PLUMAS COUNTY

The California Mines Co. has been organized to work a large mine on the Mother Lode and developing the Oakland and Osborne claims in the southern part of this county. The officials are D. C. Demarest, W. de Varila, L. H. Fordham, and H. C. Bochio of San Francisco, and two Minneapolis people.

SHASTA COUNTY

The new 100-ton decantation slime plant at the Midas mine, at Harrison Gulch, is in operation. It cost \$30,000 and is similar to the Globe mill in Trinity county. The 20-stamp mill of the Midas is running full time. Rich ore is being extracted by C. C. McDonald from his claim on Mule mountain, near Redding. He is erecting a 5-stamp mill.

SIERRA COUNTY

A gravel channel under a capping of lava has been opened by an adit driven from an old hydraulic mining area at the Mountain House property.

SISKIYOU COUNTY

A dredge is to be moved from the Oroville district to operate between Montague and Yreka. L. N. Parks will be in charge.

YUBA COUNTY

Probably the Pennsylvania and Bessie mines at Browns Valley will be unwatered and reopened.

COLORADO

CONEJOS COUNTY

(Special Correspondence.)—There is nothing much doing

PART OF CONEJOS, RIO GRANDE, MINERAL, AND ARCHULETA COUNTIES, COLORADO.

at Platoro, but it is said that the Golden Cycle people have taken hold of the Mammoth property there and will shortly start men working.

Platoro, February 27.

MINERAL COUNTY

(Special Correspondence.)—Conditions at Creede have not changed much. The Humphreys Creede United Mines Co. mill is not yet started on account of the low price of lead, and will not for some time, probably not before next summer. There is more snow here this winter than ever before in the history of the camp, but even at that there is not enough to bother working except temporarily.

The fluorspar mine at Wagon Wheel Gap is not shipping at present, as the steel mill at Pueblo is overstocked. The company is going ahead with development work and seems to think there is a lot of mineral there. It is trying to develop other markets than the steel works, and may ship to various glass works in Kansas and Texas. This deposit is remarkably pure, running well over 90% CaF without any washing or sorting, while that from Illinois and Kentucky is only about 85% or less.

Creede, February 27.

MONTROSE COUNTY

(Special Correspondence.)—The recent discovery was in Happy cañon, about 7 miles south of Montrose. As soon as news of it leaked out, everybody in that town made a break, and you could not get even a horse, much less a rig at Montrose, as they were all strung out along the road to Happy cañon. The ore occurs in a flat stratum of sandstone and gold content as high as \$60 are reported. The first car of ore was to be shipped today, and they expected it to run \$60 per ton. The American Nettle, and possibly some of the other mines just below Ouray, were in quartzite, and possibly this may be a similar deposit. Of course, there is no telling

yet whether it amounts to anything or not. There are said to be about 200 tents out there, so it is quite a boom camp. Montrose, February 27.

TELLER COUNTY (CRIPPLE CREEK)

On No. 12 level of the Isabella Mines Co.'s main shaft, a shoot 5 ft. wide has been opened by a raise, containing tellurides and averaging from \$200 to \$300 per ton. Thirty sets of lessees are working at the property. The total number of people engaged about mines in the district is 3200, of whom 2476 are miners. Lessees operating blocks of ground of the Stratton estate, under lease from the Stratton Cripple Creek Mining & Development Co., paid a total of \$61,121 in royalties during the year 1913.

IDAHO

The annual report of Robert N. Bell, state inspector of mines, has been submitted to Governor Haines, and includes the following information: There were 4000 men employed in all mines. There were 26 fatal accidents, 25 of which were in Shoshone county; also 45 serious and 75 slight mishaps. These occurred in mining 2,000,000 tons of ore and an equal amount of waste. The gross value of ore and bullion produced was about \$24,000,000 and \$4,500,000 was paid in dividends. The state again assumed first place in the list of lead producers. The coal deposits in the new county of Madison are described in the report.

BONNER COUNTY

A raise in the Idaho-Continental mine, 26 miles from Port-hill, is opening ore assaying 71.3% lead and 38 oz. silver per ton. Shipments will be made in July.

SHOSHONE COUNTY

Around Murray the snow is melting and a busy season is looked for in mining. Machinery at the National mill will be ready for a run by April 1, although that for the flotation plant is somewhat behind.

MICHIGAN

HOUGHTON COUNTY

In his testimony before the committee of inquiry into the strike, James MacNaughton, of the Calumet & Hecla, gave the following information: Probably half of the opened ground was worked out, and the other half would not be so rich in copper; the proportion of copper per ton of 'rock' in the district was about 20 lb., the Calumet conglomerate yielding 28 lb.; in Butte this was 62, Arizona 74, and the Arizona and Utah porphyrites 22 lb.; to mine conglomerate is 50 to 75% more expensive than the amygdaloid; Calumet & Hecla normally hoists 20,500 tons of 'rock' per day; from mining to marketing of copper, a period of about six weeks elapses; 300 shaftmen are employed at the Calumet & Hecla; 80% of its 70 miles of drifts are used; hoisting engineers in the district are not licensed; the contract system of mining was based on the cubic fathom, 6 by 6 ft., measured by the mine 'captain'; prices of contracts are cut down at times, but there are 750 to 800 bosses, and some may not be square with the men, this is not by the Company's orders; a bonus system of 10c. per ton exists for mining over 900 tons per month; men were required to work not more than 150 ft. apart; before the strike the Calumet & Hecla companies employed 419 one-man and 177 two-men drills; in 1912, miners with the former machine earned \$3.34, and with the latter \$2.82 per shift; trammers in 11 mines moved from 1200 to 1948 tons each per day over distances of 171 to 900 ft.; the Calumet & Hecla has had no labor troubles since 1871; Mr. MacNaughton started work in 1877 carrying water for coal shovellers.

A timberman, trammer, and finally a contract miner named Joseph Ram, gave interesting evidence before the Commission. He kept his monthly pay dockets for 17 years, and they were exhibited. From 1897 to 1902 he averaged \$2.32.

and from 1902 to 1914 \$3.41 per shift, the latter term being on contract. He worked an average of 297 days per year.

The strike in the district has been practically called off by Charles H. Moyer, president of the Western Federation of Miners.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—Estimates for the construction of a 2000-ton unit of the new leaching plant of the Anaconda Copper Mining Co. total about \$1,250,000. The ultimate capacity is to be 9000 tons per day. The plant will consist of five main sections, namely, the dewatering, roasting, acid manufacture, leaching, and precipitation of the copper. The silver is also to be saved, and salt will be added during leaching. There will be 28 6-hearth, 18-ft. diameter McDougall roasting furnaces, and ten 50 by 14-ft. tanks for the first unit. The slime plant consists of 160 28-ft. diameter Dorr thickeners, 20 20-deck 16-ft. diameter buddies, three 50-ft. diameter by 14 ft. high settling tanks, and three Oliver filters. Half of the buddies are working, and the remainder will soon be ready. The 20-ft. diameter Great Falls converter is treating 105 tons of matte at a single blow, which lasts about six hours. A second one is to be constructed.

Anaconda, March 21.

At 2200 ft. the Middle vein has been cut in the Pilot-Butte, but is low grade. The Anaconda company will have a large exhibit at the Panama-Pacific Exposition in 1915. Fifty feet

different alternating sheets of basalt and volcanic scoria. This central core has been the solution channel, and the gold and silver has been deposited over great widths in the beds of basalt and scoria, which have been favorable to ore deposition. These beds of scoria have been most favorable on account of their porous nature, but some of the softer basalt flows have also formed large deposits. So far as the work has progressed, it shows nine different basalt flows and a similar number of scoria beds. From the central core of the augite andesite the metal content decreases each way, and tonnage depends, therefore, upon the cost of production, but the commercial ore is in places at least 150 ft. wide. The ore zone, so far as proved, is about 1600 ft. long. The first 100 ft. in depth in the deposit includes practically all of the oxidized ore, which will be mined and milled first. The deposit to that point is almost vertical. It will be mined by the glory-hole system. Below this depth the deposit turns off rather flat and will be mined by the top-slice system, which is in effect the most up-to-date system of caving. No machine-drills are used, as the ore is so soft. The main haulage level from the mine is 2600 ft. long, 1750 ft. of which is underground. Transportation is by electric locomotives. The 350-ton mill is now in full operation, and was briefly described in the *Mining and Scientific Press* of September 20, 1913.

HUMBOLDT COUNTY

A 5½-cu. ft. dredge at Unionville, owned by the Federal Mines Co., is the only dredge in Nevada. It handles 1500 to 1600 cu. yd. per day. Gasoline engines are used.

Judge Farrington, in the United States District Court, on March 12 gave his decision in the Rochester mine case, wherein Dr. George and Stevens Bros. sued J. F. Nenzel, discoverer of the Rochester mine, and the Rochester Mines Co., for a block of stock which they alleged had been secured through fraud. The plaintiffs were awarded \$210,000 worth of shares.

The narrow-gage line built by the Rochester Hills Mining Co. is to be extended right into the camp.

LANDER COUNTY

The placer deposits in the Battle Mountain district are yielding good returns to the claimholders, and are attracting considerable notice. According to Will C. Higgins, editor of *The Salt Lake Mining Review*, who has inspected the place, considers it of importance. The gravel is shallow, and every facility exists for cheap transport of supplies.

LINCOLN COUNTY

A station is being cut at 1400 ft. at No. 1 shaft of the Amalgamated Pioche. A brecciated quartzite zone was entered at the bottom of the shaft, and contains enough gold and silver to warrant prospecting. Mr. Van Wagenen is superintendent.

LYON COUNTY

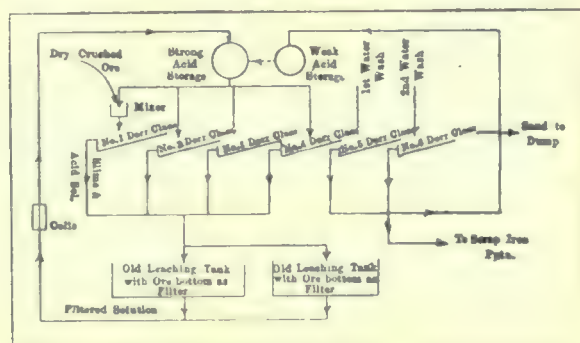

From August 1913 to January 1914 the Nevada-Douglas ore has averaged 6.5% copper, containing 3 002,516 lb. of metal, worth \$435,365.

The statement of the Mason Valley Mines Co. for the last quarter of 1913 contains the following:

| | |
|---|-----------|
| Ore smelted, company and custom, tons | 50,197 |
| Matte produced, tons | 3,610 |
| Copper content, pounds | 3,694,227 |
| Operating profit | \$53,561 |
| Depreciation, deferred charges, bond interest | 38,272 |
| Net profit | 15,289 |

MINERAL COUNTY

The Goldfield Consolidated Mines Co. has secured an option on the property of the Aurora Consolidated Mines Co. at Aurora. The latter Company is building a 500-ton mill, which is well on toward completion. This mine was examined by the Tonopah Mining Co. prior to Jesse Knight and associates buying it and building the new plant.

FLOW-SHEET OF BUTTE-DULUTH PLANT.

within the Four Johns claim of the Butte & Superior, 35 ft. of high-grade ore has been opened. During February the Butte-Duluth leaching plant treated 3200 tons of ore with 89% extraction. The copper output was 65,000 lb. of electrolytic and 40,000 lb. of precipitate.

NEVADA

CHURCHILL COUNTY

During February the Nevada Hills mine produced 4070 tons averaging \$9.99 per ton, from which was recovered \$33,273 at a cost of \$27,810. Development covered 558 ft. at a cost of 80c. per ton. Total resources are worth \$197,341.

EUREKA COUNTY

The following description of the Buckhorn orebodies is from an interview of Fred J. Siebert, consulting engineer for the Buckhorn Mines Co., by the *Reno Gazette*: The property is 28 miles south of Beowawe on the Southern Pacific railroad, where the Company's power-plant is operated. The mine was discovered in the winter of 1908-09 by Joe Lynn, whose partners were W. S. McCrea, William Ebert, James Dwyer, and John Swan. Eventually, April 1910, George Wingfield bought 14 claims and several fractions for \$90,000. Since then 20,000 ft. of work has been covered, and a large tonnage of low-grade ore opened. There is no other mine with the same characteristics. The central core of the orebody is an intruded porphyry, augite andesite, intruded through many

NYE COUNTY

Owing to some good gold and silver ore being opened about four miles north of Tonopah, a rush, among which were a number of well known local people, set in to stake claims. During the week ended March 21, ten mines at Tonopah produced 11,248 tons of ore worth \$274,610. In February the Tonopah company's yield was \$187,945 from 11,492 tons, with a profit of \$80,550. At 1640 ft., in trachyte, in the Belmont, the Belmont vein was cut. West End profits were \$36,381 from 4357 tons in February. The Extension mill is treating 157 tons per day. Net earnings of the Montana in February were \$12,000. A tube-mill, capable of preparing 15 to 18 tons per day of chaledony for use in the mills in Nevada plants, is being erected at the quarry of O. Maris, six miles from Manhattan. The Tonopah Mining Co. will compare the local and Danish pebbles for grinding. Three mills are working at Manhattan, and with considerable development under way the camp is busier than for some time..

WHITE-PINE COUNTY

The Consolidated Copper Mines Co. will probably erect an experimental mill near East Ely.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—At 900 ft. the Socorro company's drift has cut 8 ft. of \$50 ore. The monthly mill production is about two tons of gold-silver bullion, in addition to a considerable tonnage of high-grade concentrate. The Company recently retired its \$200,000 issue of preferred stock, from earnings. A good cash reserve is being accumulated. In the Pacific, the slope below 250 ft. is from 10 to 15 ft. wide, worth from \$60 to \$135 per ton. The Socorro company has an option on the property. The Oaks Co. is surveying and sampling the Eberle mine. Ore assaying \$34.80 gold and \$16.77 silver per ton has been opened in a vein off the main vein near the portal of adit 'A.'

Mogollon, March 9.

OREGON

Mining in this state has been described in 'Mineral Resources of Oregon,' Vol. I, No. 1, published by the Oregon Bureau of Mines and Geology, H. M. Parkes, director. This serial will be published regularly. The total value of all minerals in 1913 was \$3,650,000, of which \$1,925,000 was from gold, silver, lead, and copper. Josephine, Jackson, Lane, Douglas, Curry, and Coos counties, in the southern district, produced gold and silver worth \$225,000. The ratio between placer and deep mining is over 2 to 1. In eastern Oregon the output was \$1,700,000, 75% from deep mines, from Baker, Malheur, Grant, Wheeler, and Crook counties. The volume also deals with the necessity for a mineral survey, work of the bureau, 'What is the Matter With the Mining Industry?' by A. M. Swartley, coal in Oregon, and other matter.

UTAH

SALT LAKE COUNTY

Underground work at the Utah Copper Co.'s mine at Bingham has been almost discontinued, and within a few weeks will be entirely abandoned. D. C. Jackling said recently that this is a result of the advanced stage reached in the stripping operations, which makes it possible for the steam-shovels to provide even more ore than the combined capacity of the two mills require.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Ben Hur Leasing Co., in the Ben Hur mine, is working on two shifts, entirely in ore, north and south of the shaft, on No. 2, 3, and 4 levels. Recent shipments have been low grade, but the ore is improving at present. The Rathfon Reduction Co. has paid

\$5000 to Ferry county on its option for the purchase of the Republic mine. This leaves a balance of \$18,000 of deferred payments to be paid when due.

Republic, March 20.

Bids for the assets of the Republic Mines Corporation were submitted at Spokane on March 10. The property included the Lone Pine, Pearl, and Surprise mines. Robert Sterling, of Wallace, Idaho, bid \$230,000, on the understanding that he could get an option on the Quilp mine; E. R. Davidson, of Spokane, bid \$250,000, exclusive of the Quilp; Henry Kehoe, of Spokane, bid \$150,000, provided he could get the Quilp option, and certain other arrangements; Sidney Norman, representing New York people, offered \$150,000, part in cash and part in stock in a company to be formed to acquire all the producing mines at Republic, and also to erect a 50-ton concentrating plant; and E. L. Tate, of the Quilp company, offered \$150,000 under certain conditions. It is said that Mr. Sterling has under option 760,000 of the 1,000,000 shares in the Corporation. The Corporation's property was eventually sold to Mr. Sterling for \$260,000. He was acting for a New York syndicate.

The Hope and Knob Hill mining companies, operating at Republic, have purchased the mine and mill of the San Poil

SAN POIL MILL, REPUBLIC.

Mining Co., also at Republic, for \$170,000. The payments are to be made from ore from the former mines. The daily capacity of the plant is 100 tons.

STEVENS COUNTY

Foundations are being prepared for a 100-ton smelter for the Copper King Mining Co. at Chewelah. Oil will be used as fuel.

CANADA

BRITISH COLUMBIA

An option on the Yellowstone group of claims, 17 miles from tidewater up the Salmon river, has been taken by the Canadian Mining, Exploration & Development Co. W. J. Rolf is the Company's engineer.

The Granby Consolidated company's new smelter at Anyox was blown in on March 16.

ONTARIO

During February, the Dome mine's gold yield was 12,010 tons of ore for \$69,000, or \$5.74 per ton. Since April 1913 the total is 130,240 tons, yielding \$1,116,606.

A new hoist has been installed at Beaver Consolidated, Cobalt, and extensive development will be done on 10 levels. Thirteen machines are working underground at present. The La Rose company is prospecting in the Fisher-Eplett mine, north of the Beaver Consolidated, and at 300 ft. has opened a large body of quartz assaying 40c. per ton in gold. The McKinley-Darragh-Savage company, of Cobalt, has taken a six months' working option on the Jupiter mine at Porcupine.

Personal

W. DeL. BENEDICT is in California.
 THOMAS T. READ is in Washington.
 F. B. LAWSON is here from London.
 A. D. SPROAT is at Guanajuato, Mexico.
 E. H. LESLIE was at Denver this week.
 WILLIAM D. PEREGRINE is at Denver, Colorado.
 G. L. SHELDON was in Salt Lake City last week.
 JOHN RANDALL is now at Placerville, California.
 A. W. STICKNEY sailed for England on March 12.
 CHARLES JANIN has returned from Russia to London.
 ALBERT BURCH was in San Francisco for the week-end.
 WHITMAN SYMMES was in San Francisco over Sunday.
 RALPH ARNOLD passed through San Francisco last week.
 ERNEST G. LOCKE is temporarily at Hollywood, California.
 GEORGE T. COFFEY has gone back to Dawson for the season.
 H. M. WOLFLIN is visiting the mines of southern California.
 EUGENE CALLENS has gone to Johannesburg from Paris, France.
 B. N. JACKSON has removed from Cibola, Arizona, to Los Angeles.
 W. FOOTSON WONG has been visiting the Inspiration mine, in Arizona.
 WALLACE LEE has left Los Angeles and is now at Washington, D. C.
 A. B. EMERY, manager of the La Fe mine, Zacatecas, is in New York.
 EDGAR COLLINS passed through San Francisco, returning to Arizona, Monday.
 EDMUND JUESSEN was at Manhattan last week and is now in Plumas county.
 JAMES S. DOUGLAS and WALTER DOUGLAS are inspecting the Phelps-Dodge properties in Arizona.
 ELWOOD MEAD has been granted permission by the regents of the University of California to return to Australia.
 H. W. MOORE has been made general superintendent of the Tropico Mining & Milling Co., at Rosamond, California.
 I. F. LAUCKS is at Silverton, British Columbia, on professional business for the Standard Silver Lead Mining Company.
 Paul M. Paine has been appointed general superintendent of the Honolulu Con. Oil Co. properties with headquarters at Taft, California.

HYMAN HERMAN, director of the Geological Survey of Victoria, has been elected president of the Australasian Institute of Mining Engineers.

W. G. ANDERSON has been appointed general manager for the Ore Chimney Mining Co., Ltd., at Northbrook, Frontenac county, Ontario, Canada.

GARDNER F. WILLIAMS will address the San Francisco section of the A. I. M. E. on 'Modern View of the Origin of the Diamond,' at the Engineers' Club, Tuesday evening, March 31.

MORTON WEBBER has been engaged in examination work in Idaho and Montana for the past three months. He recently returned to New York for a few days, and has left again for the West to be absent about two months.

A. HOUSMAN, who died at Alameda, March 1, was best known as having been connected for some time with the State Mining Bureau. While in that office he did much of the work upon which the bulletin upon copper resources of California was based. He has also much other good work to his credit, being a well educated engineer of experience and attainments. His death is regretted by a wide circle of friends.

Schools and Societies

MASSACHUSETTS 'TECH' has a student registration of 1687, a gain of 74 over the last year.

COLUMBIA UNIVERSITY will spend \$3,721,215 in operating all of its departments from July 1, 1914, to June 30, 1915. For the work of the university proper, \$2,925,597 is appropriated, of which \$2,131,655 is for educational administration and instruction. The balance is for buildings, grounds, library, and redemption fund.

The INSTITUTE OF PETROLEUM TECHNOLOGISTS held its inaugural meeting in London on March 3. The president, Sir Boverton Redwood, was in the chair. 'The Geology of the Anticline' was discussed by Sir Thomas Holland; 'The Educational Aims of the Institution,' by Cunningham Craig; and 'Petroleum Technology as a Profession,' by Vivian B. Lewes.

The COLORADO SCHOOL OF MINES senior class trip includes the following itinerary: Leave Denver on April 20; at Midvale, Bingham, Tooele, and Salt Lake City, Utah, from April 28 to May 4, inclusive; the metallurgists' division will be at Butte and Anaconda from May 5 to 11; and the miners' division at these places to May 13. The tour will end at Denver on May 18.

The Metal Markets

LOCAL METAL PRICES

San Francisco, March 26.

| | |
|---|------------|
| Antimony | 9 — 9½c |
| Electrolytic copper | 15½—15¾c |
| Pig lead | 4.15— 5.10 |
| Quicksilver (flask) | \$39.00 |
| Tin | 40½—42 c |
| Spelter | 6½— 6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

New York, March 26.—More business is doing in copper for domestic trade and exports, and prices have advanced from 14.05 to 14.35c. per pound. Producers' agencies in London are quoting 14.67 to 14.72c. for electrolytic, according to delivery. Lead and spelter show no change and are both flat. Tin is steady at 38.55 to 38.75 cents. Bar silver in New York and London are 58c. and 26¼d. per ounce respectively. Net earnings on the common stock of the American Smelting & Refining Co. were equal to 7.47% in 1913, compared with 11.47% in 1912.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

The report of the Royal Commission on Indian Finance and Currency has been published, according to The Mining Journal, London. The Commission reports that the currency most suitable for the internal needs of India is silver and notes. On the other hand, the system can only be satisfactory if the gold standard reserve is maintained at an adequate figure. The reserve exists to secure the conversion into sterling of so much of the internal currency as may at any moment seek export. The Commission consequently suggests a rearrangement of the assets at present at the disposal of the gold standard reserve and the paper currency reserve. The gold specie, amounting to six crores of rupees, or say £4,000,000, at present to the credit of the paper currency reserve, should be transferred to the gold standard reserve in exchange for sterling securities to the same amount now held by the gold standard reserve. The silver holding of the gold standard reserve, valued at about £4,000,000, should similarly be exchanged with the paper currency reserve, which, with the total amount of gold held by the gold standard reserve, would raise that fund to about £9,500,000 in specie. This sum, however, is considered insufficient, and a minimum of £15,000,000, it is suggested, should be accumulated as rapidly as possible. This gold reserve would, of course, be kept in London. There can be no question that one of the most important financial questions of the time, especially in view of the present declining tendency of the world's gold output, is to secure that every ounce of gold is made to support as much credit as possible. In English banking circles there is a general recognition that present reserves of gold should be gradually increased, and so long as it is possible to satisfy commercial opinion that the reserves held are adequate, there seems no reason why gold should be wasted through attrition, hoarding, casual loss, or distribution into channels by which it passes out of the immediate control of central organizations, when the actual functions of currency can be discharged by notes, bills, and token coins.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

| Week ending | 1913. | 1914. |
|-------------------|-------|-------|
| Feb. 26..... | 39.00 | |
| Mch. 5..... | 39.00 | |
| Monthly averages. | | |
| Jan. | 39.37 | 39.25 |

| Aug. | | 40.50 |
| Sept. | | 39.70 |
| Oct. | | 39.37 |
| Nov. | | 39.40 |
| Dec. | | 40.00 |

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

| Date. | | Average week ending | | |

Zincblende at Joplin is selling for \$38 to \$41, basis of 60% metallic zinc, compared with \$49 to \$52, basis, for the corresponding week of 1913. Lead ore brings \$50, basis of 80% metallic lead, compared with \$57 per ton, basis, a year ago.

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations, in cents per pound:

| Monthly averages. | 1913. | 1914. |
|-------------------|-------|-------|
| Jan. | 1913. | 1914. |
| Feb. | 50.45 | 37.85 |
| Mch. | 49.07 | 39.76 |
| Apr. | 46.95 | |
| May | 49.00 | |
| June | 49.10 | |
| July | | 40.70 |
| Aug. | | 41.75 |
| Sept. | | 42.45 |
| Oct. | | 40.61 |
| Nov. | | 39.77 |
| Dec. | | 37.57 |

Billiton tin sold at public auction in 1913 at Batavia, Java, totaled 66,000 slabs averaging 74.8 lb. each, or 4,938,800 lb., at an average price of 42.61c. per pound.

Imports of aluminum, crude, ingots, scrap, etc., in December 1913 were 1,354,803 lb., valued at \$224,278; in December 1912, 3,803,469 lb., valued at \$653,401; in the year 1913, 23,185,775 lb., valued at \$3,905,977; and in the year 1912, 22,159,937 lb., valued at \$3,092,889.

COAL AND IRON IN RUSSIA

Coal production of the Donetz Basin of Russia, which provides 55.5% of the coal consumption of the country, amounted to 28,000,000 tons in 1913. At a recent conference of coal men at Kharkof, estimates were made of the output and consumption of Donetz coal for the next five years as follows: output, 34,217,000, 37,828,000, 41,132,000, 43,787,000, and 44,274,000; consumption, 33,567,000, 36,149,000, 38,280,000, 39,742,000, and 41,295,000 short tons, respectively.

The metallurgical industry of Russia, which has its principal centre in the consular district of Odessa, is showing increased activity. The output of pig iron in the country last year was 4,660,000 long tons, against 4,050,000 tons in 1912. Imports were about 50,000 tons. Orders received by the Russian Iron & Steel Syndicate in 1913 were 2,435,000 tons.—*Daily Consular Report*.

GERMAN MACHINERY TRADE

Machinery exports from Germany in 1913 amounted to 593,969 metric tons, against 536,636 tons in 1912. The average value was \$276.29 per ton. Imports were 87,902 tons, against 77,937 in the previous year. These were worth \$222.77 per ton. The exportation of machines from Germany in 1913 was divided as follows: to Russia, 19%; Austria-Hungary, 11; France, 10; Great Britain, 7; Belgium, The Netherlands, and Italy, each 5; Spain, 3.5; Rumania, Brazil, and Argentina, each 3; Switzerland, 2.5; Denmark, United States, South America (except Brazil and Argentina), and Japan, each 1.5%. The remaining 17% went to Norway, Sweden, Canada, China, India, etc. According to official data, the United States supplied 40%, Great Britain 34, Switzerland 6, Canada 7, Belgium 2, and Austria-Hungary 1.6% of Germany's machine imports in 1913. *Daily Consular Report*.

INDUSTRIAL ESTABLISHMENTS in Italy, according to the 1911 census, totaled 243,985, employing 2,305,698 people, and 1,573,774 hp. Of these, mining and metal-working industries were 63,667, employing 799,345 people and 257,776 hp. There were 495 chemical works, employing 10,165 people and 3867 horse-power.

Company Reports

BROKEN HILL PROPRIETARY MINING CO., LIMITED

During the six months ended November 30, 1913, this well known concern had the following results:

| | |
|--|-----------|
| Ore treated, tons | 158,863 |
| Refinery output: | |
| Silver, ounces | 2,750,671 |
| Lead, tons | 49,723 |
| Tailing treated by flotation, tons | 181,463 |
| Zinc concentrate produced, tons | 43,914 |
| Profit | \$691,000 |

Good progress has been made with the foundations for the iron and steel plant at Newcastle, and the work is being pushed on as fast as possible with a view to starting work early in 1915.

MACNAMARA MINING COMPANY

This Company operates a mine, 10-stamp mill, and cyanide plant at Tonopah, Nevada. The report for the past year includes the following information: Development is being done on the 500, 600, 625, and 700-ft. levels on the Lower Contact vein, and will be started soon at 800 ft. During the year, 2103 ft. of work was accomplished on this vein. Good widths of ore with good bullion contents have been opened, but the occurrences were rather irregular. In places the vein is 40 ft. wide, but averages 30 ft. High-grade ore was cut on the 500-ft. level.

| | |
|---|-----------|
| Development, feet | 3,284 |
| Ore treated, tons | 28,098 |
| Average value, per ton | \$8.41 |
| Gold yield, ounces | 2,842 |
| Silver ounces | 266,772 |
| Recovery, per cent | 92.7 |
| Gross value | \$219,002 |
| Cost per ton: | |
| Mining, including development, taxes, insurance, etc. | \$4.349 |
| Mining, including management, interest on debt, etc. | 3.523 |
| Bullion expenses | 0.136 |
| Cash at November 30, 1913..... | \$4,444 |

GOLDFIELD CONSOLIDATED MINES COMPANY

From a total of 330,217 tons of \$14.88 ore milled, and 19,248 tons of \$27.39 ore shipped, the different mines of this Nevada company produced as follows: Combination, \$1,332,957; Mohawk, \$1,765,345; Red Top Laguna, \$336,496; Clermont-Jumbo, No. 2, \$1,422,271; dumps, \$54,496; and Clermont, \$527,284. The gross value was \$5,438,853, and the revenue from ore was \$4,942,828, according to the president, George Wingfield. The expenses of mining, transport, milling, construction, taxation, and general were \$2,210,883, leaving net \$2,731,945. Two dividends, 30 and 40c. per share, amounted to \$2,491,404. Cash balances at the end of the year were \$1,074,372, with other outstanding settlements of \$161,217. The uncertainty of the Nevada bullion has been settled, and the transportation company controlled by the Goldfield Consolidated, will merely continue to work at actual operating cost. According to Albert Burch, the general manager, development covered 38,696 ft. at a cost of \$8.42 per foot. Operating conditions are becoming increasingly more difficult, as 90% of the present ore is from pillars, ends, and sides of old stopes from which the best ore was mined some years ago. Mining costs are \$3.41 per ton. Measurable ore reserves consist of 136,000 tons of average grade, and are larger than at the beginning of 1913. The mines contain large quantities of low-grade ore, which will be treated if some means of doing so is devised.

The mill costs were 17c. below those of 1912. All mill residue has been impounded since the start, and experiments show that there is a profit of a few cents per ton in them. Total costs were \$6.38 per ton, against \$6.92 in 1912. The gross output to date is 1,778,304 tons yielding \$59,475,201, and \$26,330,470 in dividends.

ASSOCIATED NORTHERN BLOCKS (W. A.), LIMITED

This Company owns 48 acres of property at Kalgoorlie, and 93 acres at Ora Banda, 40 miles from Kalgoorlie, Western Australia; and 112 acres at El Refugio, Mexico. The first-named area has produced £1,728,043 from 365,555 tons of ore to date; the Victorious, £115,263 from 102,797 tons; while owing to the revolution in Mexico, little has been done, and the mine is to be leased. Dividends, including £35,000 paid in the year ended September 30, 1913, total £726,250. The Iron Duke claim, at Kalgoorlie, is practically worked out, although tributaries mined 17,963 tons of ore, yielding gold worth £68,671. The sulphide mill treated, in all, 25,047 tons of ore, including 5923 tons of purchased ore, also 32,276 tons of residue, yielding £102,348. Royalties amounting to £16,417 were collected from tributaries. A profit of about £17,479 was made on this property. Developments at the Victorious mine have been noted in the Special Correspondence pages of this journal from time to time. Development covered 6688 ft. at a cost of \$7.96 per foot. Shaft-sinking 168 ft. cost \$84.60 per foot. Stations cut amounted to 9477 cu. ft. Three lodes produced 97,639 tons of ore worth £124,043. The country around the ore is very decomposed, causing great strain on timbers by creeps. The estimation of ore reserves is difficult, and work in the sulphide zone is not sufficiently advanced to make estimates. The mill produced bullion worth £108,370 at a cost of \$1.23 per ton. Detailed costs will be given in another issue of this journal. The report includes one made by Edward H. Liveing on the two properties in Western Australia. He gives little hope for the Iron Duke mine, and advises postponing the erection of a sulphide plant at the Victorious until No. 6 level is well developed. The year's work left a surplus of £23,867, while investments are worth £37,210. W. Martin is superintendent of the Victorious mine, and George M. Roberts general manager for the Company.

ASHANTI GOLDFIELDS CORPORATION, LIMITED.

This Company controls a large concession, and operates mines and treatment plants in the Gold Coast Colony, West Africa. The directors' report under review covers the year ended June 30, 1913. The reduction works treated 148,447 short tons of ore, yielding 107,977 oz. gold, and 7296 oz. silver, realizing a total of £476,800, with the bullion from 14,661 tons of old tailing. The working profit was £253,116, but on adding sundry receipts and deducting government royalty, depreciation, development, etc., the net profit was £175,147. The balance from the previous year was £76,169, which gave a total of £251,315. Three dividends, amounting to £187,507, were paid out of this total. Ore reserves at September 30 were estimated as 365,300 tons, worth £1,505,000, with a profit of £573,600. These are 27,540 tons less, but worth £24,000 and £21,300 profit respectively above those of the previous estimates. Working costs in West Africa averaged \$6.24; bullion charges, 19c.; London expenses, 28c.; government royalty, 74c.; development, \$1.29; and depreciation 66c.; a total of \$9.40 per ton. Gas-engines have been installed at the mines in place of steam power. The directors considered the present state of the mines to be highly encouraging, the profit in sight shows no decrease, and the metallurgical methods have improved.

The consulting engineer's, W. R. Feldtmann, report, covers the year ended September 30, 1913. Development at all mines covered 18,278 ft. The Ayernm mine produced

25,782 tons of ore, yielding £47,500. This came from No. 5 level stopes, and a little from No. 6 level. The lode below No. 4 level has been dangerous to mine. The main shaft is down 565 ft., and drifts at this depth have opened the vein, which is quartz in irregular lenses of a low grade. There is 105,000 tons of ore in this mine. The Ashanti mine produced 77,207 tons, yielding £318,000. Ore reserves are 182,300 tons, averaging \$28.60 per ton. The Obuasi shoot on No. 10 and 11 levels has opened excellent ore. The Justice claims produced 16,720 and 6170 tons of oxidized and sulphide ore, respectively, returning £31,000 and £10,900. Blackie's mine yielded 12,897 tons and £33,500 in gold. A considerable amount of work was done on outside properties with varying results. There was a large shortage of labor during the year, hampering work generally. Mr. Feldt-mann's report gives great detail of mining and future profits. Treatment of the different ores produced consists of roasting and direct cyaniding, and a filter-press plant, showing recoveries of 92.6 and 80.14%, respectively. Some of the Ashanti ore contains graphite.

YUKON GOLD COMPANY

This Company operates dredges and hydraulic plants near Dawson, Klondike, dredges at Iditarod, Alaska, and a boat on the American river, California. The report of O. B. Perry for the year 1913 gives the following information: No. 4 and No. 6 boats in the Klondike were dismantled, and are being rebuilt on other areas. The cost of moving them and constructing power-lines was \$164,484. The eight Dawson boats worked from May 1 to October 31, a season of 164 days. The average recovery and cost was 65.13c. and 29.53c. per cubic yard, respectively. Owing to power troubles with the Granville Power Co., the boats were idle 20 days, or 11% of the possible time. The power contract is to be canceled, and power will be obtained from the Yukon Gold Co.'s own plant. Of the area mined at Dawson, 445,624 sq. yd., or 68.4%, was frozen and had to be thawed by steam. The Iditarod dredge worked from May 8 to November 25, a season of 203 days. The average recovery and cost was \$1.67 and 64.33c. per cubic yard, respectively. The two California boats, two at Oroville for a time, and later one at that place and one near Auburn, worked satisfactorily. The latter has a capacity of 120,000 cu. yd. per month. Hydraulicking at Dawson resulted in a loss, due to stripping the top gravel before the 'pay' could be mined. The water-supply fell from 524,249 miner's inches in 1912 to 406,135 in 1913. The area blocked out and stripped could not be completely mined and the gold recovered. About 50% remains to be cleaned to bed-rock, so the gross value is not representative of the area mined, or of the gold content of the gravel. The cost was 9.7c. per cubic yard, and duty of the water 6.6. Drought, using water for generating power, and a bad break in the ditch system were responsible for unsatisfactory hydraulic work. Scattered claims leased to individuals gave a good profit. Results may be summarized as follows:

| Work done. | Cubic yards. | Gold yield. | Cost. | Profit. |
|--------------------------------|--------------|-------------|-------------|-------------|
| Dawson dredging... | 5,133,575 | \$3,343,667 | \$1,515,872 | \$1,827,795 |
| Dawson hydraulic- ing | 2,875,952 | 256,491 | 278,917 | *22,426 |
| Iditarod dredging... | 496,756 | 827,420 | 319,560 | 507,860 |
| California dredging... | 2,550,271 | 176,023 | 103,849 | 72,174 |
| Miscellaneous | | 185,800 | 33,756 | 152,044 |
| Total | | \$4,789,403 | \$2,251,955 | \$2,537,449 |

*Loss due to causes explained.

Royalties paid were \$787,278; amortization, \$520,886; interest, general, \$145,373; a total of \$1,453,536. A dividend of 6% was paid. The indebtedness to the Guggenheim Exploration Co. was reduced by \$425,000. The surplus at December 31, 1913, was \$489,576.

HOMESTAKE MINING COMPANY

In point of dividends paid, this Company stands fourth in the list of the world's gold mines, being exceeded by the Crown Mines, and East Rand Proprietary group in the Transvaal, and the Goldfield Consolidated of Nevada: but when its scale of operations and future is considered, it probably occupies first place.

The report of T. J. Grier, superintendent, covers the calendar year 1913, and contains the following information: Development covered 16,313 ft. of drifts and 686 ft. of raises. The depths of the shafts remain as they were a year ago, namely: Ellison, 1850 ft.; B. and M., 1550; Golden Prospect, 1100; Golden Star, 1400; Old Brig, 800; and Golden Gate, 800 ft. Broken ore in the stopes amounts to 2,206,671 tons, an increase of 176,000 tons. The property is in fine physical condition, and prospects point to a long and profitable life. A modern change-house was erected for the miners, and Recreation Building at Lead was built and is now ready for all of the Company's employees. Assets of the Company are worth \$23,811,776, which includes all equipment, cash, and bullion. Liabilities include capital stock, \$21,840,000; accounts payable, \$2942; outstanding drafts, \$492,713; unclaimed dividends, \$5660; and profit and loss balance, \$1,470,460.

Results may be summarized as follows:

| | |
|---|-------------|
| Ore treated, tons | 1,540,961 |
| Average value realized, per ton..... | \$4.0148 |
| Gold output | \$6,186,652 |
| Balance from 1912 | 1,455,958 |
| Other revenue | 132,716 |
| Total revenue | 7,775,326 |
| Costs: | Per ton. |
| Mining and 'dead work'..... | \$1.480 |
| Milling | 0.254 |
| Cyaniding sand, direct cost | 0.104 |
| Regrinding | 0.009 |
| Cyaniding slime | 0.086 |
| Assay office | 0.021 |
| Foundry and shops | 0.061 |
| Shafts | 0.137 |
| Hydro-electric plant and electric operation..... | 0.028 |
| Hospital, Recreation Building, etc..... | 0.106 |
| General, including property purchase, taxes, timber, water, salary, survey, etc..... | 0.434 |
| Total cost | \$2.720 |

Dividends totaled \$2,146,224, equivalent to \$1.39 per ton, and total realizable value per ton was \$4.0148. The discrepancy is due to other sources of income. It is also to be noted that these figures are based upon tons milled, which does not agree with tons mined. It is impossible with the figures at hand to state separately the actual cost of milling and mining per ton, nor is there any information given as to total ore reserves or recovery. Both are known to be satisfactory, since the reserve is sufficient for many years, and the tailing loss is understood to be about 24c. per ton. It is to be noted that at the Homestake much construction is charged into cost and not capitalized, although recently new capital was issued against the cyanide plants, water system, hydro-electric plant, and other work that has been under way for some years back. As we noted at the time, the excess profits, above regular dividends, are divided between stockholders and workers, the latter receiving a 7% dividend on each man's pay for the year. The Homestake is a great mine, and the management is doing excellent work. It is to be regretted that the accounts as published are somewhat inadequate, and we should like to see them classified more in detail. However, we believe this is not due to any indisposition to give stockholders and public all proper information.

Book Reviews

IGNEOUS ROCKS; COMPOSITION, TEXTURE, AND CLASSIFICATION; DESCRIPTION AND OCCURRENCE. By Joseph P. Iddings, Vol. II, 8vo, xi + 685 pages. New York, John Wiley & Sons, Inc.; London, Chapman & Hall, Ltd., 1913. For sale by the *Mining and Scientific Press*. Price \$6.

Volume II is a worthy successor to the earlier volume of Mr. Iddings' 'Igneous Rocks,' and to the mining man, interested in the broad relations of ore occurrence, is of greater interest. Volume I, which appeared in 1909, describes successively the chemical composition of igneous rocks and the minerals which compose them; the physical chemistry of magmas; the crystallization and the texture of igneous rocks; their mode of occurrence; the process of magmatic differentiation, and the classification of igneous rocks.

Volume II is devoted to a description of the composition of igneous rocks, both chemical and mineral; their texture and their genetic relations. The latter entails a knowledge of the mode of occurrence; their relation to other rock masses; their geographical distribution, and a determination of the period of the earth's history when they solidified. The treatise is separated into two parts: "one dealing chiefly with the description of the material features and their modes of occurrence as rock masses, petrography in its narrower sense; the other part treating of the occurrence of groups of igneous rocks in all regions of the earth." The first chapter is devoted to a resume of the character of igneous rocks as solidified liquid solutions, the presence of gradational facies between all rock types, and the advance in petrography due to the introduction of the quantitative system of classification. As to date the latter system has not been in sufficiently long or general use by petrographers to serve as the foundation of a description of the igneous rocks of the world, Mr. Iddings introduces a qualitative classification.

Descriptions of the various igneous rocks follow, arranged according to this classification, in which Iddings recognizes rocks composed of (1) quartz preponderant; (2) quartz and feldspar; (3) feldspar; (4) feldspar and feldspathoids (nepheline, leucite, and sodalite); (5) feldspathoids; (6) mafic minerals (amphibole, pyroxene, olivine, iron ores, etc.). Under each are described first the phaneritic (crystalline) rocks, and then their aphanitic (porphyritic and glassy rock) equivalents. The numberless names which have been applied to various rocks as described by previous petrographers of each division are defined, and the origin of the name explained. Notwithstanding the advantage in the quantitative classification of rocks in the treatment of certain petrographic problems, the mining engineer must depend on a selected few of these old fashioned and to him practical rock names. Class No. 2, for example, includes granite, quartz-monzonite, granodiorite, quartz-diorite, and quartz-gabbro. Mr. Iddings, in attempting to give to each name a definite rock significance, introduces certain quantitative limits which can be followed with advantage even in petrographic work of a roughness such as suffices for most economic work. He places in division No. 6, for instance, gabbros, in which the feldspar minerals (pyroxenes, hornblendes, olivines, etc.) exceed the salic (feldspar, etc.) by more than 5 to 3. More feldspar-rich gabbros belong to Division No. 3. Under each division the characteristics of the minerals composing the rock members thereof are described, as are the rock textures. A discussion of the chemical composition then follows, the volume containing over 2000 rock analyses.

Part II begins with the description of the distribution of igneous rocks in the world with generalizations particularly upon petrographical provinces. The difficulties partly inher-

ent to the problem itself and partly due to the absence to date of sufficient data, are emphasized. The major structural and petrographic features of each continental land mass and the principal island groups are then discussed. After the description of the igneous rocks, that of the petrographical provinces of each land unit follows. Maps, on a small scale to be sure, of the Americas, Europe, Asia, Africa, Japan and the East Indies, Australia, and the islands of the Pacific, show the world distribution of igneous rocks. Naturally, because of the author's nationality, and because of the wealth of American petrographic data, America is particularly fully described. No matter, however, what continent or what political division thereof may be for the moment of interest to the mining engineer, he will find a digest (with citations to the most valuable literature) of our knowledge concerning the local igneous rocks. It is this regional description of igneous rocks which the mining world will find of most interest and value. Certain ores and non-metallic products are known to be confined to certain igneous rocks; each of us in addition has a distinct impression that still other useful substances are prone to be associated with certain classes of igneous rocks. Nowhere else, to the reviewer's knowledge, is there so much material by which such associations, some of which have become axiomatic can be applied, while others still hypothetical, can be tested.

S. H. B.

AMERICAN RED CROSS ABRIDGED TEXT-BOOK ON FIRST AID. Miners' Edition. By Charles Lynch and M. J. Shields. P. 186. Ill., index. P. Blakiston's Son & Co., Philadelphia, 1913. For sale by the *Mining and Scientific Press*. Price, 30c.

This useful and practical text-book is similar to the earlier editions of the Red Cross first-aid books, but contains much additional information and instruction. It is designed to be a manual for miners and for the use of instructors of miners. The first 132 pages of the book are devoted to physiology and explanations of the symptoms and treatment of all kinds of injuries that may be caused by accidents, such as sprains, dislocations, fractures, wounds, bleeding, and electric shocks. Such subjects as freezing, drowning, gas poisoning, artificial respiration, and bites of insects or reptiles are also covered. The subject of 'Miners First-Aid' is confined to one chapter of 42 pages, of which 28 pages are photographs showing how mine accidents may be caused by carelessness or negligence. Although this book does not treat extensively of mine accidents, it gives simple and efficient instructions for the treatment of persons who have met with injuries from any source.

FIRST AID IN MINING. By Louis G. Irvine. P. 114. Ill. South African Red Cross Society. Johannesburg, 1913. For sale by the *Mining and Scientific Press*. Price, 60c.

This valuable little hand-book is supplementary to the regular series of First-Aid Manuals, and contains specific information regarding accidents occurring in mines. It is not intended to be a complete text-book, but rather as a series of notes and additional information which will be of service in the treatment of injuries sustained in and about mining properties. The book contains specifications for emergency stations and first aid equipment; rules for the treatment of wounds, bleeding, burns, sprains, and fractures; and methods for the transport of injured men underground. There are also important chapters treating of accidents due to poisonous gases, electricity, and cyanide poisoning. The explanations, directions, and illustrations dealing with the treatment of wounds and fractures, and the transportation of the injured, are especially clear and simple. The working drawings of the Red Cross plank stretcher should be of great value to every mine superintendent. The various methods of artificial respiration are excellently described and illustrated. The book should be in the hands of all of our mine operators, for a practical knowledge of the treatment of injuries can only be acquired by means of a thorough study of the subject.

Decisions Relating to Mining

ORE ON DUMP—PART OF REALTY

Where purchasers worked a mine under an option, and, after making the required payments to the owner up to the date of expiration, allowed their option to expire and forthwith entered into a new agreement with the owner it was held that ore which had been extracted and left on the mine dumps while working under the first option, became a part of the soil and subject to the provisions of the second option.

Savage v. Nixon (California), 209 Federal, 122. October 9, 1913.

OIL AND GAS LEASE—FORFEITURE

Plaintiff's grantor executed an oil and gas lease to defendant to run for 40 years under which defendant was only bound to pay 1% of the net proceeds derived from oil or gas obtained, should he see fit to develop the land, and in so doing obtain oil or gas. Held that an unexplained delay for a period of 18 months on the part of the lessee in commencing development operations was sufficient to work a forfeiture of the lease, there being no consideration for the lessor's agreement either in the way of money paid or work done by the lessee.

Davis v. Riddle (Colorado), 136 Pacific, 551. November 10, 1913.

RIGHT OF SUBJACENT SUPPORT—HOW WAIVED

Where the owner of land retains the surface estate and conveys the estate in minerals thereunder, he may convey or waive the right of subjacent support for the surface, but such conveyance or waiver should not be implied unless the language of the instrument is appropriate therefore and clearly indicates such to be the intention of the parties to the conveyance. Damages allowed to a lessor of coal lands whose lessee under a mining lease had removed so much coal as to cause the surface to cave and fall in.

Walsh v. Kansas Fuel Co. (Kansas) 137 Pacific, 941. January 10, 1914.

MINERAL RIGHTS—TAXATION

The assessment for taxing purposes of mineral rights where they have been separately conveyed and are owned by persons other than the owners of the surface, without any corresponding deduction from the assessments against the surface owners does not violate U. S. Constitution, 14th Amendment, as discriminating against the owners of mineral rights so assessed, where it does not appear that mineral rights known to exist were consciously relieved from taxation if they belonged to the owners of the surface.

Downman v. Texas (U. S. Supreme Court). Dec. 1, 1913.

Brown Bear Coal Association, 42 Land Decisions, 320. August 13, 1913.

MINING LICENSE—FORFEITURE SET ASIDE

Where landowners granted a mining license to other persons to mine upon their property for a period of five years, and the licensees entered into possession, and expended some money in sinking a shaft and extracted a small quantity of ore, and where said licensees suspended their operations for a period of several months thereafter and then renewed them for a further period, the licensors will not be permitted after acquiescing in all these operations to arbitrarily terminate the mining license on the grounds that there had been a suspension of work at one time during the period, nor to exact a higher royalty than was originally agreed upon as a condition for allowing the licensees to continue work.

Gates v. Steeple (Missouri) 161 Southwestern, 1185. December 11, 1913.

Recent Publications

RUSSIA. A handbook on commercial and industrial conditions. By John H. Snodgrass and other consular officers. Special consular report, No. 61. P. 255. Maps. Department of Commerce. Washington, 1913. As its name implies, this publication covers everything of interest connected with Russian enterprises in Europe and Asia.

STATISTICS ON COPPER AND COPPER MINES. Compiled by J. C. Wilson & Co., Mills building, San Francisco, 1914. P. 16. This is a handy little booklet and contains details of copper production of the world, the principal producing states of America, consumption of the metal, new uses, average prices, and dividends paid by American copper companies in 1913.

WATER SUPPLY, SEWERAGE, AND DRAINAGE DEPARTMENT OF WESTERN AUSTRALIA. First annual report, 1912-13. H. C. Trethowan, under-secretary. P. 101. Ill., maps, charts, plans, index. Perth, 1913. In 1912, the goldfields water supply, metropolitan water supply, agricultural water supply, country towns, irrigation drainage, artesian boring, water supplies, and stock routes in mining districts, and other state organizations for similar purposes, were consolidated under the name of the above department. The combined capital expenditure of these important undertakings is \$32,000,000, employing 771 people. The report under review contains the past year's work and present position, and extracts, especially of the goldfields water scheme, which cost \$15,800,000, will be published in other issues of this journal.

United States Geological Survey publications, Washington, 1913:

INTERPRETATION OF ANOMALIES OF GRAVITY. By Grove Karl Gilbert. Professional paper 85-C. P. 9. Map.

MINERAL RESOURCES OF THE UNITED STATES, 1912. Part II. Non-metals. P. 1218. Maps. The different chapters in this valuable compilation have already been extensively covered in this journal during 1913, as they were published in pamphlet form by the U. S. Geological Survey. Authors on the various subjects were as follows: E. W. Parker, B. Hill, David T. Day, Charles A. Davis, E. F. Burchard, Jefferson Middleton, J. H. Hance, Ralph W. Stone, A. T. Coons, T. Nelson Dale, Frank J. Katz, Frank L. Hess, Charles G. Yale, Hoyt S. Gale, W. C. Phalen, James M. Hill, J. S. Diller, Douglas B. Sterrett, Edson S. Bastin, and George C. Matson.

GEOLOGICAL ATLAS OF THE UNITED STATES. U. S. Geol. Surv., Folios 185. Murphysboro-Herrin; 187, Ellinjay; 188, Talula-Springfield; 189, Barnesboro-Patton; 190, Niagara. Washington, 1912-1913. The geological atlas that is being published by the U. S. Geological Survey is issued in the form of elaborate folios, one for each quadrangle or group of quadrangles as they are surveyed. Each includes topographic and geological maps and a brief text. The maps illustrate the great refinement that has been attained by the Survey in its cartographic work, and the folios constitute the standard source of information for the areas they cover. The Murphysboro-Herrin and the Talula-Springfield folios were prepared in cooperation with the Illinois Geological Survey, and the Barnesboro-Patton with that of Pennsylvania. In each case the mapping has included platting structural contours which, in connection with the topographic sheet, are of the greatest value in opening and developing the various coal beds and other mineral deposits. The Illinois folios are especially interesting because they represent the extension of this method into a flat area where the surface is heavily drift covered. The results are highly creditable to both the state and national surveys concerned.

Recent Patents

1,080,721.—METHOD OF TREATING MATERIALS WITH SOLUTIONS OF TITANOUS SALTS. Christian M. Edward Schroeder, Rutherford, N. J., assignor to The Titanium Alloy Manufacturing Co., New York, N. Y., a corporation of Maine.

The method of bleaching materials which comprises immersing them in a bath containing metallic titanium and an acid solvent of titanium.

1,080,606.—CONVERTER PROCESS. Otto Thiel, Landstuhl, Germany.

Introducing a portion of the pig metal into the converter, then subjecting the charge to the blast and allowing it to remain in the converter, then introducing more of the charge into the converter and then subjecting the combined charge to the blast to the end, until finished.

1,080,573.—STEAM TURBINE. John F. Metten, Philadelphia, Pa., assignor to the Wm. Cramp & Sons Ship & Engine Building Co., a corporation of Pennsylvania.

The combination in a turbine with a rotor, a casing having a removable segment, and a dished diaphragm having a packing around the axis of the rotor, of a separate nozzle carrying element, and means whereby the nozzle carrying element engages the casing and the diaphragm to lock the latter against longitudinal movement.

1,080,656.—CENTRIFUGAL PUMP. William K. Richardson, Leavenworth, Kansas.

In a centrifugal machine, the combination with a rotor adapted to subject fluid to pressure due to centrifugal force, of a plurality of blades in position to deliver fluid into the eye of said rotor and revolve therewith, said blades being inclined toward the rotor in a direction opposite to the direction of rotation, and having a calculated translatory displacement approximately twice the rated volume designed to pass the screw.

1,080,707.—ROCK DRILL. Edwin M. Mackie and Percival F. Doyle, Franklin, Pa., assignor to Chicago Pneumatic Tool Co., Chicago, Ill., a corporation of New Jersey.

In combination with a rock drill, an air feed device co-operating therewith, a valve for admitting pressure fluid to the air feed, and a fluid pressure actuated governor for controlling the degree of pressure admitted to such device, said governor having provision for releasing such pressure therefrom.

1,074,150.—PROCESS OF TREATING MATERIALS. Frederick W. Yost, Chicago, Illinois.

Treating finely divided metal-bearing material capable of undergoing propagative reaction, which comprises initiating a reaction in a mass of the material, conducting a current of reaction-supporting gas through the mass in one direction, conducting another current of reaction supporting gas through the mass in another direction and controlling conditions so as to cause propagative reaction between components of the currents of gas and of the mass.

1,080,586.—ROASTING FURNACE. Charles W. Renwick, Isabella, Tenn., and Nicholas L. Heinz, LaSalle, Ill.

Ore roasting furnace of the class described, the combination with a hollow rabble-shaft and hollow rabble-arms of L shaped tubular ports vertically extended in the shaft and arranged in different radial planes, connections for the arms with the shaft comprising slotted coupling pieces on the shaft in conjunction with rods extended through the arms, and means at the outer ends of the arms for putting the rods under tension in said coupling pieces and for releasing the same.

Industrial Progress

The NATIONAL TUBE Co. announces publication of bulletin 15A. dealing with National pipe for drilling purposes.

THE WM. POWELL Co. has for distribution a 'Powell White Star Valve Booklet,' which contains full descriptions of this well known line of valves.

The HARDINGE CONICAL MILL Co. announces that it has received an order from the Beatson Copper Co., at Latouche, Alaska, for five of the largest sized Hardinge conical mills.

ARTHUR G. MCKEE is distributing a catalogue describing and illustrating in detail the 'Baker' suspension type storage bin as built by him in wood, steel, or concrete for any one of many uses.

THE LAIDLAW-DUNN-GORDON Co. has issued under date of January 1914, Bulletin L 523-A, containing complete descriptions of 'Cincinnati' gear duplex Corliss steam driven air-compressors classes WA and XA, made by that company.

THE FRED M. PRESCOTT STEAM PUMP Co. has published in the form of bulletin 106 the record of a duty test made on a 'Prescott, Duplex Missabe Waterworks Power Pump' at Dubuque, Iowa, which showed an overall efficiency of 83.5 per cent.

IN LESCHEN'S HERCULES for February is a well illustrated account of coaling United States warships at sea, as also of how wire rope enters into rapid steel frame construction, logging, handling gravel and sand from a pit, and various other uses.

The copper smelting and converting plant of the Yampa Smelting Co. at Bingham Canyon, Utah, which was of 1000 tons daily capacity has been purchased by the MORSE BROS. MACHINERY & SUPPLY Co., which will dismantle the entire plant and all of the material is offered for sale.

SAUERMAN BROS. are supplementing their regular and well illustrated catalogue of the 'Shearer & Mayer' drag-line cable way excavator with individual leaflets of 4 by 7 in. size punched for convenient filing in standard loose-leaf note books and illustrating various situations in which the excavator is being used to advantage.

THE SWEETLAND FILTER PRESS Co. is now ready to send inquirers copies of catalog No. 10, containing a complete account of the new 'Sweetland Self-Dumping Filter' of the clam-shell type. In this filter the leaves are enclosed in a horizontal steel cylinder of which the lower half is hinged and so arranged as to drop back out of the way when the filter is to be discharged.

The ARIZONA ENGINEERING Co. has just been incorporated for the purpose of doing a general engineering business and handling mining supplies in Mohave county, Arizona. The incorporators are E. F. Thompson; J. E. White, former manager at the Quartette mine; G. R. Franklin, purchasing agent for the U. S. Stores Co.; and R. P. Wheelock, county engineer. The principal place of business will be at Kingman.

The SPRAGUE ELECTRIC WORKS has issued catalog 329 dealing with electric fans and Bulletin 49,000 describing the portable ozonators made by that Company. Fans are widely used for ventilating purposes nowadays. The ozonators are designed for use in situations where for any reason a ventilating system is impossible. They act upon the principle that ozone, an unstable form of oxygen, readily unites with organic matter in the air and so purifies it.

IRON as well as petroleum are to be developed in China through American enterprise. It now develops that the Bethlehem Steel Company participates in the concession recently granted to the Standard Oil Company and acquires rights as to iron ore lands. Following the incursion of this Company into Chile, this indicates a far seeing policy designed to acquire raw materials for a world-wide manufacturing and selling industry.

MEXICAN bank notes are being put out that rest on the security given by rubber stamp signature and a gaudy official seal, according to reports from the Mexican capital. This new brand of currency is being turned out by the print shops of Mexico City and its validity secured by an edict, making a refusal to accept it punishable by fine and imprisonment. If the presses do not break down under the strain, a happy solution of Don Victoriano's financial difficulties has at last been found.

DEPRECIATION for exhaustion of orebodies as mined at "a reasonable rate not to exceed 5 per cent," allowed under the United States income tax law, does not predicate complete amortization in 20 years, as a little reflection shows. Assume an orebody of which one-twentieth is mined each year. On each twentieth as mined, a 5 per cent depreciation is allowed. At the end of 20 years all the ore is gone, and only 5 per cent in all has been allowed for amortization. It is difficult to see how mining companies are to be taught proper accounting and shareholders brought to regard dividends from mines as in part return of capital, if the United States continues to set such an example.

QUESTIONS as to the persistence of ore in depth are among the most vital that come up in connection with any mining proposal. It is rarely that a mine can be bought for the ore in sight, and estimation of the value of most mines, as all prospects, must be based upon the judgment as to the depth to which the ore may be safely assumed to persist. We have published numerous articles upon this subject, and this week we present a general summary by Mr. Malcolm MacLaren that appeals to us, particularly since it is not a generalization based upon all ores, but a careful consideration of the effect of depth upon particular

types of gold ores. This, we believe, is the right way to approach the problem. Mr. Maclaren's paper was presented to the International Congress of Geologists at Toronto. It rounds out nicely various contributions made by him earlier to our own columns, and will, we are sure, be read with interest.

JAPANESE newspapers are protesting at the terms of the contract recently entered into between the Standard Oil Company and the Chinese Government: it is considered that the provision that in event that the fields first to be prospected prove barren, other territory is to be opened to the Company, practically creates a monopoly and violates the 'open door' principle. Not having the terms of the agreement before us, we are unable to judge as to the merits of this criticism, but we do believe profoundly that development of the oil resources of China under present conditions can only be safely undertaken by a large and experienced organization working under monopoly or near monopoly conditions. Any other plan is certain to be wasteful of capital and oil; and in the long run somebody pays for the waste.

WALKING down a city street is one of the most dangerous occupations if one may judge from the number of accidents and deaths reported. For example, there were 2,099 killed and 42,544 injured in street accidents in Great Britain in 1913. Of these, 579 were killed and 18,365 injured in the metropolitan district of London alone. These figures may be compared with the 2360 killed in the coal mines and 661 killed in the metal mines of the United States in the same year. Exact comparisons are impossible, since the total number exposed to accident in the streets is unknown. It does seem clear, however, that the accident rate in the mines is decreasing while the reverse is true of street accidents. Motor cars are responsible for a marked increase in the death and accident rate in the cities, though in the city of London proper the number of deaths from this cause has begun to decrease. Apparently nature is working in the usual way; the clumsy have been killed and the survivors have learned to dodge.

JUST to let our friends in other states and lands know that the supposed protest of the Pacific coast cities against the repeal of the Panama canal free tolls provision for coastwise ships is not unanimous, we want to say that the straight forward, plain spoken message of the President has received the approval of a large part of the more thoughtful citizens resident on the west coast. A loud protest is being made in certain quarters, but it should not be taken too seriously. There would be much political gain to many now in sorry plight if the President could be 'put in a hole.' Without unduly discounting the honest, but as we believe mistaken, convictions of others, we think this the prime impelling force back of the furore. When the free passage of coasting vessels was proposed, senti-

ment was naturally for it. California was still smarting from the inflictions of the ancient railway monopoly aided by the pretended competition of the Pacific Mail Steamship Company. It was hard to believe that the day for such things had passed, and the cry for absolute freedom of the water route had not only sentiment but business to commend it. In the interval since the power of the Interstate Commerce Commission and of the various state commissions to regulate rates and prevent abuses has been placed upon a wholly unexpectedly secure basis. The power of the courts to dissolve a monopoly has been shown, and there is much less reason to fear a return to oppressive tactics by transportation agencies. No one was more surprised than the Westerners when England and other countries took the ground that the new law violated treaty rights. It had seemed, and still seems, to relate to a matter that is entirely one of domestic concern. However, the whole world apparently thinks us wrong in this, and Californians no more than other Americans relish being considered treaty violators, whether the charge be just or unjust. Conditions having changed and the economic argument being now unimportant, there is strong sentiment in favor of giving up as a courtesy what might, if necessary, be defended as a right.

METALLURGY is really chemistry applied to the business of making dollars out of ore, and the art owes much to the chemists who have contributed so much to its advancement. Not long ago we chronicled the advance which Mr. W. A. Hall has made toward the solution of the vexing fume problem, and this week we print the specifications of the patent taken out by Mr. E. R. Weidlein covering the process which he has devised for the recovery of copper from its ores by leaching. The research work on which this is based having been done in the Mellon Research Laboratories of the University of Pittsburgh, which have been widely exploited in the popular magazines. Too much may perhaps be expected of it, just as the son of a famous father is at some disadvantage. Substantially this same process is covered by United States Patents 723,949 (1903), and 930,967 (1909), and Mr. Weidlein's hope is therefore to succeed where others have failed. To carry out the suggested process of precipitating the copper from CuSO_4 solution by passing SO_2 into the warm solution under pressure, it is necessary to first neutralize the excess of acid present and this is not only an appreciable item of cost, but presents great difficulty. It is suggested that this can be done with limestone, but anyone who has had practical experience in the neutralization of sulphate solutions with lime or limestone is painfully aware that the resulting hydrated sulphates of calcium precipitate go back into solution and re-precipitate with slight changes of temperature and pressure in a most annoying and disconcerting manner. This is only one of the difficulties, and while the process does not involve the consumption of sulphuric acid, it must not

be overlooked that the collection and compression of SO_2 , followed by passing it through the solution, involves an appreciable cost. The management of the Mason Valley plant has always had the best reason for giving out details of practice—well directed and successful work—and it is greatly to be desired that, even if the proposed process shall not prove as successful as is hoped, yet a full record of the results attained will be made public for the guidance of others. Nothing is more futile than the laborious re-acquiring of other people's fruitless experience. We recently mentioned that a European company is about to abandon a process after two years' work upon it and take up another which has similarly been tried and abandoned by an American company, which is about to take up the first process. It is quite possible that, under the different conditions, this is exactly the right thing to do, but what an amount of profitless labor could be avoided if each company were possessed of a full record of the results attained by the other. Success is not the only praiseworthy thing; well directed effort is equally honorable; and their duty toward their fellows should impel metallurgists to make public, in so far as they reasonably and honorably can, the fruits of their experience.

Diamonds and Diamond Mining

Diamonds are a luxury, and while the world is prosperous, the mining of this form of carbon is profitable, according to Mr. Gardner F. Williams, who gave a most interesting illustrated lecture on the subject before the San Francisco section of the American Institute of Mining Engineers on March 31. Before the financial depression in the United States in 1908, the Kimberley group of diamond mines employed 4000 whites and 27,000 kaffirs; but during this period these numbers were reduced by 2000 and 10,000 respectively. After many years of careful study of diamonds, Mr. Williams has no definite theories regarding their origin. Peculiar combinations of diamonds and other minerals have been found, and were shown on the screen during the lecture. An early theory of their formation advocated especially by the late H. Carvel Lewis was that the carbon came from the shales around part of the diamond 'pipe' or blue ground; but this theory has difficulties to meet. Previous to the discovery of the Kimberley deposits, all diamonds had been found in rivers, and river diamonds differ from those mined at Kimberley.

A large percentage of the Kimberley stones are broken, and those from each mine have distinctive characteristics; but so expert are the valuers that they can identify them at once. Open-cut mining was continued to a depth of 1000 feet, but it then became dangerous, and underground work is now being done to 3520 feet. Hoisting at one shaft is done at the rate of 1000 'loads', of 1600 pounds each, per hour. It was found that the hoisting ropes whipped about in the shaft and cut the timbers, but steel is now being used

in place of them, and to prevent this cutting the ropes, hoisting is done at a great speed, the ropes thereby being kept taut as a rod. The blue ground is spread out on large areas of 'floors' to a depth of 10 inches, and after over a year or two it disintegrates so much that 66 per cent will pass a 16-mesh screen. During the washing and concentration of the blue ground, the diamonds are recovered on grease tables. Why they are caught, and practically nothing else, is explained by Mr. Gardner by the fact that diamonds are not wet by water, and therefore stick to the vaseline used. On Page 597 of this issue, will be found an abstract of the annual report of the Premier Diamond Mining Company, Limited, showing the scale of operations at this other great South African mine, and its low costs.

The Mining Code Commission

The Smoot bill proposing a commission to codify and suggest amendments to the United States mining laws, has been reported to the Senate. In revised form it provides for a commission of three "two of whom shall be lawyers of large experience in the practice of mining law and one a mining engineer who shall have had practical experience in the operation of mines." This commission is to hold hearings in the principal mining centres in the Western United States and Alaska, to consider the experience and laws of other countries, and to submit within a year a tentative code applying to mineral lands of all classes. The members are to be paid \$500 per month and expenses and an appropriation of \$25,000 is made to cover the expense involved.

We believe that the amendments made by the Senate committee materially improve the bill. There is a widespread feeling that it is still capable of betterment, principally in that provision should be made for a larger participation by mining men. The final law will necessarily be written by some member or members of Congress, and there are so many capable lawyers in that body, including a number who have had extended experience in practice of mining law, that it may be safely assumed that the proposed code will be put in good form before it becomes a law. The main duty of the commission will be to determine what are the real defects of the present system and how far it is wise to go in attempting to correct them. This calls for experience in mining, and now that the bill has been broadened to cover coal, oil, gas, phosphate rock, and similar materials, it would seem especially important to have the commission so constituted as to draw upon experience in both the main branches of mining, that relating to metals and the non-metallies. It would be a grave responsibility for one mining engineer to represent the whole mining industry in such a work. A commission of five is not too large in view of the work to be done, the short time allowed, and the fact that it is not expected that the whole time will be devoted to the task. We believe that the real sentiment and experience of the mining world can be felt out better by mine

operators and engineers than by lawyers. After it has been determined what to do, the lawyer will have the very important task of determining how it can be done with the minimum of disturbance of our present legal fabric. It will be no easy task, and the phrasing of the law should be left wholly to those who are expert in that art. By the same rule, the determination of the wants and experience of the mining men may appropriately be left to those who feel the wants and have the experience.

The change in the phrasing of the bill, so as to charge the commission with the duty of studying the laws governing non-metallic mineral lands, renders it inappropriate that the legislation now before Congress and designed to establish a leasing system for coal, oil, and phosphate lands, be passed in advance of the report of the commission. Public sentiment is rapidly coming to favor, or at least to acquiesce in, legislation such as that proposed, but there are important difficulties yet to be met. Contrary to the implication of the press reports, the Ferris bill now before Congress, proposes not to deal with the withdrawn lands. In the case of petroleum, at least, the real difficulties are now with lands that have been reserved, but are actually developed, or are being claimed, by locators. It would seem better to work out the lines of general policy first and then provide for its application as rapidly as possible, to the cases where there is already trouble.

What is the Matter with the Rand?

South Africans have been much disturbed at the decrease in the gold yield of the Rand and are holding many a solemn inquest. The *South African Mining Journal* has been running a series of articles on 'What is Wrong with South African Mining?' In the issue of February 21 it is urged that the Government should offer more liberal terms on leases so as to induce the opening of more mines. At this distance it would seem to us a poor policy to open more mines when stamps are hung up and plants are already idle because of lack of labor, and when one, at least, of the difficulties is that capital has been too easily obtained in the past. All mining districts, even the largest, come to a time when decreasing grade of ore requires lower operating costs. The easy way to meet the situation is to increase the plant and distribute fixed charges over a larger tonnage, at the same time that by shortening the life of the property the total sum spent in annual salaries is decreased. It requires, however, nice judgment to do this without disaster. The need ordinarily arises when the mine or district is doing well and when it is easy to obtain money. If the new money be charged to capital account, satisfactory operating costs are obtained and these last long enough, in many cases, to allow those chiefly concerned to sell their holdings, but not much longer. Such at least has been the history of many a good mine. The production of metal, however, must go on regardless of changes in stock ownership, and the engineer

on the ground has then the very practical problem to face of how to reduce the real costs. It is this situation that the Rand engineers must face. They have further a peculiar difficulty in that the enormous scale of operations, in proportion to the population, calls for a labor supply that simply does not exist; taking into account racial prejudices that, rightly or wrongly, forbid opening the field freely to the labor market of the world. The mines of the Rand must have more labor or more efficient labor. The former is, at present, out of the domain of practical politics; the latter points the way to long years of effort and raises troublesome questions as to what would be the future relations of the white and black races in South Africa, if the black men were trained and educated to real efficiency.

The American way of meeting the situation would be to train some black men and use more white men. We are by no means prepared to say that that plan would meet the situation in South Africa. Our race problem, even in the southern states, is no such problem as exists on the Rand, and we have by no means made such a success in solving our problems as to warrant preaching to others. At the same time, we may be permitted to point out that in proportion to the work accomplished in the past century, the United States has been chronically short of labor. Our captains of industry have had to develop machinery and relatively efficient workmen because men of any sort were scarce. Despite the large investment, immense scale of operations, and the use of 'cheap' labor, Rand costs, while low, are not too low. Making allowance for the 'phantom profits' of which Mr. T. A. Rickard has written effectively in *The Mining Magazine*, the cost is at least 20 shillings per ton. At the North Star mine in California, a gold-quartz vein is worked which in thickness, dip, and depth of workings resembles greatly the Rand bankets. The ore is mined, hoisted, crushed, and treated by amalgamation and cyanidation, as on the Rand. A trifle over 100,000 tons per year is handled and the cost is just about 20 shillings. At the Empire mine nearby, Mr. George W. Starr, who formerly operated on the Rand, manages a similar mine, and, while detailed figures are not made public, it is known that the cost is at least as low as at the North Star. This work is all done with white labor, working 8-hour shifts, under union conditions, for \$3 per shift and above. Comparisons of cost made also with thin vein coal mining in various European countries, as well as with metal mines in general, raise grave questions as to whether the 'cheap' labor of the Rand is really cheap.

It is to be anticipated that the output of the Rand will decline in any event. To open more mines would be simply to rob the others of workmen. To increase the units of output from existing mines seems hardly possible save by the old fashioned plan of increasing the input of labor, and an American may be permitted to 'guess' that this will only be done by increasing the efficiency of the workmen in one way or another.

The Incaoro Gold Mine and Mill, Pallaya, Bolivia

By FRANCIS CHURCH LINCOLN

The Incaoro Mines Company of Delaware is operating a gold quartz mine and mill at Pallaya, near Yari, district of Larecajas, department of La Paz, Bolivia. Horace G. Knowles, formerly American minister to Bolivia, is president of the Company, and David G. Bricker, once of Butte, is general manager.

Pallaya is 117 miles from the city of La Paz, and the trip to the mine ordinarily consumes three days. One day in the saddle may be saved by taking advantage of the weekly stage to Achacache. After ascending rapidly from La Paz at an elevation of 11,800 ft. to Alto with one of 13,200 ft., the stage crosses the tableland of the Alto descending slowly to the shores of Lake Titicaca, 12,500 ft. above sea level, and skirts the lake to Achacache where the first night's stop is

made. The remaining two days of the trip must be made on muleback. On the second day, the continental divide is crossed into Amazonian drainage territory, and the descent made to the town of Sorata nestling in the valley of the San Cristobal river at the foot of the beautiful snow peak of Illampu and at an elevation of only 8,500 ft. On the third day, a quick ascent is made to an elevation a mile greater than that of Sorata, three high passes, each over 15,000 ft. are crossed, and a slight descent made to the camp at Pallaya.

Pallaya is situated on the eastern slope of the Andes, in a glacial valley facing the north and surrounded by rugged slate mountains. The general appearance of the camp is shown in Fig. 1. Its elevation, 13,650 ft.,

FIG. 1. GENERAL VIEW OF INCAORO.

places it well above timber line, so grass and flowers constitute the sole vegetation. The elevation also renders the climate cold, and the situation on the eastern side of the Andes renders it wet. In winter there are clouds of fog nearly every afternoon, and in summer it rains almost every day. The climate is therefore unfavorable to man, and the lack of timber and fuel is a handicap to mining operations, but on the other

FIG. 2a.

hand the heavy rainfall supplies an abundance of water which may be utilized for power.

The country rock is a black non-fossiliferous slate, classified by d'Orbigny as of Silurian age. At a short distance from the mine, strata of fine grained gray quartzite are interbedded with the slate, while at a distance of more than a mile, andesite dikes occur. The sedimentary rocks throughout the district have been closely folded and greatly contorted during the process of mountain building.

The ore deposits are bedded veins which have been folded with the country rock and have developed most peculiar shapes as will be seen by reference to the sections shown in Fig. 2a, 2b, and 2c. In some respects, these veins resemble the saddle reefs of Bendigo, Australia, and of Nova Scotia, but in others they are unique. Quite frequently a single vein presents the appearance of a series of parallel veins as a result of erosion of the edges of the folds, as shown in Fig. 2b, and the final result of such erosion is to produce the curious elongated orebody shown in Fig. 2a. No faulting is apparent, but during the folding process parts of a vein have at times been squeezed apart for short distances or pressed together into huge irregular masses. On the whole, however, the veins retain their widths and continuities to a remarkable extent and make it appear likely either that the folding process was a slow one which gave the vein quartz time to recrystallize as it bent, or that silicious solutions were present to heal the breaks with fresh quartz as fast as they were formed. Some of the veins are undoubtedly nothing more than quartzite strata more or less replaced by vein quartz, and it is possible that all are of this character, although no unaltered quartzite has as yet been found in the vein mined.

FIG. 2b.

FIG. 2c.

The principal vein mineral is quartz, always accompanied by some white mica and native gold, and occa-

FIG. 3. MINE, MILL, AND TAIL.

sionally also by arsenopyrite, pyrrhotite, and pyrite. The gold is occasionally visible to the native eye, most frequently in the quartz, but occasionally also in the

slate or intergrown with the arsenopyrite. When not visible to the naked eye, colors are obtained on panning. The arsenopyrite and pyrite have high refractory gold content, but are present in such small quantities as to be relatively unimportant.

The present producing vein is in an anticline of black slate, one side of which has been eroded till one leg of the vein is partly exposed. This vein is a wide one, and was quite extensively worked by the ancients. They left some pillars and a large amount of fillings containing gold. Mining at present consists mainly in the removal of these fillings and pillars, a task which sounds easy, but is in reality somewhat difficult owing to the extremely irregular crumplings and distortions which the vein has undergone. Development has been pushed beyond the ancient workings, and good faces of solid ore have been opened up to supply future needs.

About 100 Aymara Indians are employed in the mine, but this number is greatly reduced immediately after pay-day, and also when feast days are in process of celebration in neighboring villages. The wages paid vary from Bs. 0.40 (\$0.16) for the smallest boys to Bs. 4 (\$1.60) for mine captains. Work begins at 6 a.m., but is stopped from 9 till 9:15 to permit the Indians to chew coca, again from 11 to 11:30 for lunch; and still again from 2:30 till 2:45 p.m. for coca; and ends at 5:30 p.m. The working day is therefore $11\frac{1}{2}$ hours long with 1 hour off for rest and refreshment. Some of the development work is performed by contractors, who are supplied with steel,

FIG. 3. STORE, AND MANAGER'S HOUSE.

FIG. 4. DETAILS OF ROOF CONSTRUCTION.

FIG. 5. PLAN OF ROOF.

FIG. 6. VIEW OF MILL, SHOWING ROOF CONSTRUCTION.

but furnish all else themselves. They are paid at the rate of Bs. 30 per linear metre (\$3.66 per linear foot) of drifts and cross-cuts. Holes are sometimes paid for at the rate of Bs. 0.10 (\$0.40) per inch when in quartz, or Bs. 0.05 (\$0.02) when in slate.

An inclined gravity tram is employed to lower ore from the mine to a large storage bin, whence it is wheeled to the mill as required. Fig. 3 gives a general view of the mines, trams, and mill. The amalgamating mill is of the Hardinge type and has a capacity of upward of 50 tons per day of 24 hours. Power is furnished by a 24-in. Pelton water-wheel which receives its water by pipe-line from a glacial lake a mile distant and 700 ft. higher. When the ore arrives at the mill, it is dumped upon a 3½ by 7-ft. grizzly with 7/8-in. spaces between bars. The undersize falls directly into the mill-bin, while the oversize is first crushed in a 7 by 14-in. Buchanan jaw crusher. From the bin, the ore passes into a 4½ ft. by 13-in. Hardinge conical ball-mill, which reduces it to a maximum size of about 1¼ in. The pulp then enters a 6 ft. by 22-in. Hardinge conical pebble-mill, which reduces it to about 30 mesh. The pebble-mill pulp is led over amalgamating plates, of which there are two sets of 4 by 5-ft. plates each. Concentrating tables are soon to be added to save the concentrates, which though small in amount are high in value; and in the near future a second unit is to be added to the mill, thus doubling its capacity. A peculiarity in the construction of the mill building is well worth noting. Instead of using steel or timber trusses to support the roof, the trusses are ingeniously constructed of iron pipe as shown in Fig. 4, 5, and 6. The walls of the mill building, as of all other buildings in the camp, are constructed of slate.

The gold bricks obtained from the mill are very pure, running from 796 to 902 fine in gold, from 93 to 161 in silver, and 19 to 43 in base metals. The bricks are sold to the Bank of the Bolivian Nation, and will be used in coining the recently authorized Bolivian gold coins.

A Government Coal Mine

According to the *Reclamation Record* the coal mine on the North Dakota Pumping Project mined 34,365 tons of coal in 1913 at a total average cost to date of \$1.76 for both operation and maintenance. The total average was reduced 12.1c. during 1913. The average cost for coal mined in 1911 was \$1.56; in 1912, \$1.89; and in 1913, \$1.438. It is expected to reduce the average cost at least 20c. per ton during 1914 and at the same time improve the condition of maintenance. This reduction will mean \$2000 on the annual production of 10,000 tons and a corresponding reduction in operation cost.

Bank notes were issued by the first Ming emperor of China, Hung-Wu, in 1368-1399 A. D.

Costs at the Victorious Mine

The Associated Northern Blocks operates this mine and a mill at Oro Banda, forty miles from Kalgoorlie, Western Australia. The mine is opened to No. 6 level, and the oxidized ore and country are soft, giving trouble with creeps and necessitating heavy timbering. The sulphide zone has not been opened to any great extent yet, although shipments to the Kalgoorlie sulphide plant have been made for testing purposes. The mill consists of a rock crusher, four 5-ft. Huntington mills, grinding pans, agitators, and Ridgway filters, all driven by suction gas engines. During the past fiscal year the plant treated 97,639 tons of ore yielding gold worth \$519,000, with 88.6% extraction. The mills crushed 77.5 tons each per day. The three filters averaged 90.4 tons each per day, forming cakes in 6 to 7 minutes, and washing them in 12 to 14 minutes. Magnesia in the ore gave trouble with the filter-cloths, added to which was 8 to 10% solids in the water used. At first, water was added to the solution sump, but this was changed to feeding it to the mills. Cloths now last from 6 to 8 weeks. The ore contains a large quantity of silicate of magnesia, rendering settlement difficult, the thickener product rarely being over 40% solids. Costs are as follows:

| Mining: | Per ton. |
|---|---------------|
| Development | \$0.41 |
| Stoping | 0.47 |
| Hoisting and transport | 0.30 |
| Timber, waste filling, maintenance..... | 0.34 |
| Supervision | 0.05 |
| General charges | 0.02 |
| Total mining | \$1.59 |
| Milling: | |
| Breaking and storage | \$0.05 |
| Milling | 0.47 |
| Pumping and grinding | 0.02 |
| Agitating and cyaniding | 0.18 |
| Vacuum filtration | 0.15 |
| Precipitation and clean-up | 0.06 |
| Disposal of residue | 0.03 |
| Power | 0.14 |
| Supervision | 0.07 |
| General charges | 0.05 |
| Total milling | \$1.22 |
| General expenditure | |
| Sundries | \$0.01 |
| Salaries, office, etc..... | 0.13 |
| Fire and accident insurance | 0.04 |
| Bullion charges | 0.03 |
| Total general | \$0.21 |
| Total costs | \$3.02 |

The Victorian Government, Australia, owns and operates a coal mine at Wonthaggi, about 60 miles from Melbourne. During the four years ended November 23, 1913, the total output was 1,535,212 tons of coal, exclusive of that used at the mine and sold to mines. Wages paid in that time amounted to \$2,736,000.

The Persistence of Ore in Depth

By MALCOLM MACLAREN

*A study of the recent literature of ore deposits inevitably forces the conclusion that workers in this branch of geology are endeavoring, in their zeal for the advancement of knowledge, to wrest from the scanty data available more than the simple facts warrant. Data that have been garnered from the examination of a given metalliferous deposit, and that have a real value when applied to the construction of a sound theory of deposition for that metal alone, have been transferred to stay and brace the tottering structure built for another metal, with which the first may eventually prove to have only the slightest genetic affinity, however closely allied they may appear to be today. When all the known facts concerning the deposition of any one metal have been collected, collated, and analyzed, then, and not until then, may comparison be made with the data of another metal similarly treated. Some metals—for example, tin and copper—clearly lie so far apart genetically that no confusion of data has resulted, but the general impression appears to be that the data concerning the ores of other metals are interchangeable. They may often indeed be so, but the time has not yet arrived when transfers may be made with safety. For this reason, therefore, the ores of one metal only, namely, gold, are considered in the following brief review.

What Is Depth?

As a preliminary, a definition of 'depth' appears to be necessary. Here it is assumed to cover only the (presumably) primary ore that lies beneath the zones of secondary enrichment (oxide and sulphide) and to extend for a limited depth, say 1000 ft., below the bottom of the deepest mines, or 6000 ft. in all. To take the enquiry deeper is to enter the barren zone of speculation. The combined depths of the oxide and sulphide zones of enrichment may vary with climatic conditions from a few feet to a few hundred feet. Ordinarily, below 500 ft. we are, for most gold ore-bodies, in the primary zone. A word may be said in regard to the use of the term 'primary ore.' It comprises that ore for which we know no prior state of combination and no former locus in space. In this review then, depth is understood to be a zone extending downward from 500 to 6000 ft. below the earth's surface. The ore in this zone may be assumed to have been deposited during a single short geological era, and to owe nothing to accretions of a widely separated and later period. It is probable that the irruption of auriferous solutions was normally paroxysmal in character and indeed was comparable to volcanic eruptions of the present day. Only those fissures and channels

that were open at the geological moment, so to speak, were filled with ore. An assumption of this nature may help to explain the vertical variations in the tenor of the ore in the primary zone, where in many mines, horizontal bands of richer and poorer ore alternate. These alternations conceivably represent the varying horizons at which successive upward pulsations of metalliferous solutions either became sufficiently cool to be deposited or met with fluid agents of deposition.

A Simple Classification of Deposits

I have elsewhere¹ attempted to show that the gold deposits of the world fall naturally into well defined auriferous groups, the members of each group, though widely separated in space, being closely allied in genesis, in character, and in geological age. One of the most important distinguishing characters of the several groups is persistence (or otherwise) of ore in depth. The classification adopted must therefore be outlined.

PRE-CAMBRIAN

| Occurrence. | Examples. |
|--|---|
| (a) Arising as the end-product (generally following albite-porphyry) of diabasic magmatic differentiation series intrusive into schists. | Western Australia (Kalgoorlie, etc.), India (Kolar, Hutti, and Dharwar), Rhodesia, Transvaal (Witwatersrand, Pilgrim's Rest, Barberton), Brazil (?), Guianas, Appalachian fields, eastern Canada (Porcupine, etc.). |

PERMO-CARBONIFEROUS TO POST-JURASSIC (?)

| | |
|---|--|
| (b) Arising as the end-product of granodioritic intrusions. | (a) Urals. (b) Eastern Australia and Tasmania. (c) Western North America (California, Oregon, and Alaska). |
|---|--|

MIDDLE TERTIARY

| | |
|--|---|
| (c) Associated with andesite volcanic eruptions. | Northern Chile, Peru, Colombia, Mexico, California (Bodie), Nevada, Utah, Colorado, Unalaska, Japan, Sumatra, Celebes, New Zealand, and Transylvania. |
|--|---|

The above table slightly varies from that originally adopted, but four years further field experience has enabled me to abolish the former tentative subdivision of the pre-Cambrian deposits and has given a much clearer view of the general sequence of events leading up to auriferous deposition in that age. These groups, therefore, contain all the important gold deposits of the world. Two of these, the pre-Cambrian and the Tertiary are extremely well defined; the third, including all apparently dependent granodioritic magmas, is still somewhat indefinite and will certainly be modi-

*Read before the International Geological Congress at Toronto.

¹Maclaren, 'Gold,' London, 1908, pp. 42-75.

fied with increase of knowledge. Probably, when the exact age of its auriferous impregnation is known, the Ural chain of deposits will be brought into close accordance with the eastern Australian, while the California (Mother Lode, etc.) occurrences may eventually be transferred to the Tertiary andesite group, with which they are indeed orographically closely connected.

In any consideration of the question of the persistence of gold ore in depth the foregoing divisions must be kept closely in mind, since the recurrence of the evidence of the complete dependence of gold deposits on geological conditions, both for deposition and for extension, lateral and vertical, is certainly the most salient feature arising from the study of the goldfields of the world.

The Andesitic Gold Deposits

It will probably be most convenient to first consider the younger goldfields. These are the andesite fields that have furnished some of the greatest bonanzas that have been known. Their petrological range is from pyroxene-andesite to quartz-trachyte, and occasionally to rhyolite, all apparently the differentiation members of dacitic magma. Their geological range is from Eocene to Pliocene with a special development in the Oligocene and Miocene. With one notable exception they follow very closely and are confined to the so-called 'Pacific Circle of Fire', with which line of volcanic activity they have clearly a very close genetic connection. The outstanding feature of gold deposition in this group is its modernity and its consequent intimate association with existing volcanic phenomena. The geographical exception is the Transylvanian goldfield of Hungary, the andesites of which were erupted during the Aquitanian stage, and along lines of crustal weakness initiated in the Oligocene and indicated at the present day by the active volcanoes of the Mediterranean.

Auriferous deposition in this group has probably been closely associated with solfataric action. MacLaurin has indeed shown that the hot springs of the solfataric region of New Zealand at the present day bring to the surface and deposit notable quantities of gold and silver in the silicious sinter that forms on the edges of the boiling springs. A similar deposit is recorded from near the De Lamar mine, Idaho. The New Zealand hydrothermal region is on the same line of crustal weakness as the goldfields of the Hauraki peninsula. On it, only 40 miles away from Rotorna, is the famous Waihi mine, until three years ago one of the greatest of the world's gold mines. The chalcidonic character of the silicious filling of the veins of many andesite fields also appears to point to a deposition from hot waters. In andesite and allied rocks in the neighborhood of auriferous veins 'propylitization' is universal. In this facies of the original andesite rock the feldspars and ferro-magnesian silicates have been converted to quartz, sericite, calcite, epidote, chlorite, serpentine, and pyrite.

The outstanding feature of auriferous orebodies in andesitic fields is their general irregularity, both in form and tenor. The great persistent fault fissures so often found in older and deeper seated rocks are unknown, or, at any rate, have not served as loci of deposition. There is nothing in any andesitic field comparable, for example, with the Mother Lode fracture of California.

It is, of course, conceivable that strong fault fissures could readily have been formed, but it is improbable that in any active volcanic and solfataric region, such fault fissures would remain open for any length when large quantities of cementing igneous and aqueous matter were being brought to the surface along the assumed line of weakness. The Comstock Lode with a total length of two and a half miles is probably the longest fault-fissure lode of economic importance in the andesitic fields. Normally the fissures of andesitic fields appear to be local tension fractures due sometimes to cooling and sometimes to minor local movements. They are therefore limited both in linear and in vertical extension, falling into the group of 'gash veins' of an old nomenclature. When two or more local series of fractures intersect, the 'stockwerk' so characteristic of many New Zealand and Transylvanian areas results.

Where the veins of the stockwerk are sufficiently close together a great bonanza may result as in the case of the Shotover and Caledonian mines, Thames, New Zealand. The original irregularity of the andesite fissures is greatly accentuated by the selective action of auriferous solutions that replace the fissure walls with ore.

Non-Persistence of Young Deposits

No andesitic field has as yet carried its bonanzas to great depths. By far the deepest is the Comstock where shafts were sunk to 3300 ft., but though ore was found erratically distributed through the lower workings, it was in no wise comparable to the great bonanzas that occurred between the 1000 and 1800-ft. levels. Only a few mines in andesitic regions have carried rich ore below 1000 ft., and the characteristic feature of even these is uncertainty of persistence in depth. For the lack of persistence a definite reason may very often be given, namely, the change along the downward course of the lode from dacite or andesite to the underlying basement rock, or, in rarer cases, to a member of the andesitic differentiation series unfavorable to gold deposition. Often the mere approach to the basement rock connotes impoverishment of lodes. Instances are numerous, for example, in New Zealand (at Coromandel and Thames), in Colorado (at Cripple Creek and Telluride), in Transylvania (at Vulkoj, Korabia, and Nagyag); but there are many lodes that persist in a homogeneous rock, which may be either a member of the andesitic differentiation series or may form a member of the basement complex through which andesites have burst, and that nevertheless, show a marked diminution in value at

comparatively shallow depths, often less than 500 ft. For some of these impoverishments a physical cause may be advanced, namely, approach to the bottom of the fissure of tension; but for others, indeed for the great majority, no such explanation is possible. For example, the Comstock fissure is well defined as far as it has been followed downward. The great Martha Lode fissure (Waihi) persists as strongly as ever below 1000 ft., but whereas above that level the gangue was mainly quartz, below it the matrix is calcite. The Martha Lode appears to have been originally wholly a calcite lode that was attacked by solfataric waters above 1000 ft., silica with accompanying gold almost completely replacing the calcite. Either, then, 1000 ft. below the surface marks the horizon at which solfataric waters become active agents of solution and deposition or, and more probably, the percolating waters had no access to a zone of the lode immediately below the 1000-ft. level. Whether at greater depths they used the lode-fissure as a channel and replaced its calcite gangue, future exploration alone can show. Here, as has so often been the case, the solution of the question of the persistence of ore in depth depends on economic considerations.

Cause of Impoverishment

The impoverishment of the veins of the andesitic goldfields in depth is a feature so universal that a general cause for diminution in value must be sought. I have attempted to show elsewhere that the probable form in which gold travels in solution, in depth at least, is not as the chloride, but as an alkaline auro-sulphide, and that pyrite and other sulphides are not the natural precipitants in depth but that precipitation may be due to a more general cause as cooling of uprising solutions.² Recently Victor Lenher,³ to whose laboratory researches field workers are deeply indebted, has shown that the alkaline sulphide solutions are highly efficient carriers of gold, that pyrite has no effect on their contained gold and that their gold is readily precipitated by acid waters or by exposure to oxidation. Both these agents may reasonably be assumed to operate only near the surface, especially in volcanic regions. Maclaurin found that the waters of the acid lake on White island, New Zealand, contained 5.47% of free hydrochloric acid. Little proof of the existence and wide distribution of acid waters at the earth's surface in solfataric regions is, however, necessary. While the former cause probably operates directly in andesitic regions proper, deposition of gold in the numerous cases in Colorado, Nevada, Transylvania, and elsewhere, in which the gold-quartz veins lie in older sedimentary or plutonic rocks, is more likely to be due to oxidizing waters, the influence of which naturally reaches only a short distance beneath the earth's surface.

Recognition of the irregularity and lack of persist-

ence of auriferous orebodies in andesitic fields is of prime importance to the mining engineer. For such orebodies not a single ton of ore more than has been actually proved may be assumed.

The Granodiorite Deposits

The second group of the classification already outlined includes those goldfields that are apparently genetically connected with granodioritic or closely allied magmas and that occur as a product of their differentiation. This group contains three geographical provinces: Eastern Australia, California-Alaska, and the Urals. For the purpose of the present paper they may also be divided simply into (a) lodes in granodiorite and allied rock and (b) lodes in the sedimentary complex through which the granodiorite is intrusive. The relations of the former are simple. Those of the latter are greatly complicated, from the present point of view, by changes in tenor likely to take place when lodes pass in depth from one member of the complex to another.

The deposits of the eastern Cordillera of Australia are initially dependent on great granodioritic intrusions that have taken place along an axial line of earth folding. Gold-quartz veins may occur in the igneous rock itself or in the sedimentary strata overlying or adjacent. The habitus of the gold deposits in the north is, in the main, in the granitoid rock; while in the south gold-quartz veins are generally found in sedimentary rocks. Important exceptions to both rules occur and are of special value as evidences of the general genetic connection between the gold deposits of the north and the south, respectively. The general age of the plutonic intrusion is probably late Permo-Carboniferous. All adjacent strata of greater age may therefore carry auriferous veins. Charters Towers in north Queensland with a production of nearly £29,000,000 is the most important field in the granitoid rocks. Its igneous complex comprises rocks ranging from gray hornblende granite to tonalite, the latter being the predominant rock. The two principal lodes are the Brilliant and the Day Dawn, which have been worked to depths of 2500 to 2700 ft. On the whole, the ore has shown a gradual though small diminution of tenor in depth. Similar fields are those of Croydon (Queensland), and Wyalong (New South Wales); neither furnish any evidence bearing on the point in question.

Ores in Sedimentary Rocks

Considering the number and great importance of the goldfields of eastern Australia developed in sedimentary rocks the light thrown by them on the general question of persistence of orebodies in depth is singularly little. Certainly some, as Gympie (Queensland) and Ballarat (Victoria), depend for auriferous deposition on the intersection of lodes or quartz veins and graphitic bands in sedimentary strata, a condition which is not necessarily recurrent at depth. Others, including the majority of the important Victorian

²Maclaren, 'Gold,' London, 1908, pp. 38, 78, etc.

³Econ. Geol., Vol. VII, 1912, p. 744.

fields and the Hargraves field in New South Wales, are developed in tension fractures between unlike beds at the crests of anticlines forming the famous 'saddle reefs' of Bendigo and Castlemaine. In these fields saddle reefs are successively met with in depth when sinking on an antilinal axis, so that a condition ensues very different from that met with when considering the filling in depth of a single continuous fissure. But the experience gained on these formations all tends to show that the lower saddles are not nearly so rich or so large as those above. At Bendigo mining operations were carried to 4614 ft. below the surface in the New Chum mine, but it is very probable that, taken as a whole, work on the Bendigo field below 2500 ft. has not been profitable. Certainly the tenor of the ore has decreased in depth.

In the California-Alaska belt of gold lodes which are apparently dependent on granodiorite magmas, the various Mother Lode mines and the Alaska Treadwell group in southeastern Alaska are the most important. The latter are still shallow and are of no help in the present discussion. Many of the Mother Lode mines, especially in Amador county, are nearly 2000 ft. deep and some, as Kennedy (3650 ft.), Gwin, (2650 ft.), and South Eureka (2850 ft.), have reached much greater depths.

The Mother Lode

The Mother Lode is a fissure zone that may be traced from Bridgeport in Mariposa county to near the northern boundary of Eldorado county, a distance of 120 miles. In many places it is a solid lode 100 ft. wide, but often it is merely a shattered zone in which numerous quartz stringers are developed. It is undoubtedly due to major faulting developed along a line parallel with the axis of the Sierras during the uplift of those mountains. The faulting has selected the softest beds (Mariposa slates) of the sediments and has uplifted them for great distances. So far as my three months' examination of the Mother Lode permitted I have not been able to make out any appreciable diminution in tenor in depth. Many mines have certainly 'bottomed' the ore in given fissures at depths less than 2000 ft., but it often happens that two or more parallel lodes occur within the Mariposa slates and that when one becomes barren a hanging wall or foot-wall lode may carry ore to much greater depths. In few auriferous regions is cross-cutting from wall to wall of the lode channel more necessary; in few has less been done than along the Mother Lode. The mines of Angels Camp are often instanced as evidence of the occasional non-persistence of Mother Lode mines in depth, but, assuming for the moment that no ore occurs there in depth, their evidence cannot be admitted against Mother Lode mines. They are, it is true, on the line of the Mother Lode fissure-zone, but, from the Hardenburg mine south of Jackson to near the Rawhide mine south of Tuttletown, the Mother Lode fissure-zone, keeping a straight course, leaves the Mariposa slates, which curve to the west

through the Gwin mine and run parallel for many miles before rejoining the fissure-zone south of Stanislaus river. One of the factors (the presence of carbonaceous slates) that makes Mother Lode mines is therefore lacking at Angels Camp. While, therefore, any given fissure of the Mother Lode series may cease to yield ore in depth it is probable that ore will be found at greater depth in another adjacent member. Finally when broadly considered, the Mother Lode may, with unchanged geological conditions, be expected to carry ore with undiminished tenor to and perhaps beyond the limit of 'depth' set forth in this paper.

No evidence of value is to be derived from a study of the gold veins of the Urals. They are nearly all small and irregular and no deep mining has been done on them.

Reviewing the scanty evidence furnished by the granodioritic group, we find for eastern Australia a gradual though small diminution of the tenor of ore-bodies in depth, while on the Mother Lode all the evidence points toward a general persistence in depth for typical Mother Lode mines. A mining engineer, dealing with the future of these mines, would not, therefore, unless he had evidence of an approaching change in geological conditions, be justified in disregarding all ore except that 'in sight'; some might be expected to occur below the deepest present explorations, and such ore should always be taken into economic consideration.

The Ancient Orebodies

The third group of the classification includes all pre-Cambrian goldfields and comprises the most important now being worked. These lie in two geographical areas, one on the borders of the Indian ocean, ranging from Western Australia through southern India and Egypt to Rhodesia and the Transvaal, and the other along the eastern side of America from eastern Canada through the Appalachian chain and the Guianas to Brazil and Tierra del Fuego. The former is a very well defined group of goldfields that, though geographically widely separated, present so many points of similarity that a geological description of the various rocks and of their internal relations in any given region would serve, with the mere change of place names, for any other region of the group. The members are consequently believed to form a single petrological and metallogenetic province, for which the appellation Erythrean⁴ has been suggested.

A typical pre-Cambrian field is that of Kalgoorlie in Western Australia. Its total gold production has been more than forty millions sterling. I have closely studied this field and find that it throws considerable light on the general question of auriferous deposition in pre-Cambrian rocks and on the persistence of ore in depth in those rocks. Briefly, the area is one of ancient schists (mainly calc-schist) through which a quartz-

⁴Maclaren, *Trans. Inst. Min. Met.*, Vol. XVI, 1907, p. 15.

dolerite magma with its differentiation products have intruded. The differentiation sequence appears to have been quartz-dolerite (quartz-diabase) followed first by members as basic as peridotite and then by more acid segregations ranging through porphyrite to final albite-porphyry, the last being often intrusive through the quartz-dolerite. Auriferous impregnation followed closely on the intrusion of the albite-porphyry. Rich lodes have been developed only in shear zones in a broad dike of quartz-dolerite, the shear zones being barren when they pass in depth or in linear extension out of the quartz dolerite. Since the shear zones are, when considered over depths of 3000 ft., approximately vertical, and the quartz-dolerite dike which is parallel to the strike of the shear zones dips west at 65° , the shear zones pass in depth out of the dike, the eastern shear zones with their contained lodes reaching barren ground sooner than the western.

Kalgoorlie, therefore, well illustrates an outstanding feature of all goldfields, except indeed some in the Tertiary group, namely, that non-persistence of ore in depth is a function not of depth but of geological structure. In Kalgoorlie three well defined parallel shear zones may be made out. Taken severally and having regard to the depth factor alone, they show (a) non-persistence of ore in depth (Australia East and Lake View-Perseverance lodes), (b) persistence of ore in depth (Great Boulder and Ivanhoe-Horse-Shoe lodes), and (c) a probable enrichment in depth (Ivanhoe West lode).

Depth Alone Misleading

Generalizations based on the depth factor alone when geological conditions are unknown are misleading. T. A. Rickard⁵, for example, has relied on the evidence furnished by the failure in depth of the eastern lodes and an impoverishment in the Ivanhoe mine at 2500 ft. to support a general theory of impoverishment in depth. F. L. Garrison⁶ also quotes the Ivanhoe impoverishment as possible evidence of non-persistence in depth. The Ivanhoe impoverishment does take place, but it is local and is due to the fact that the vertical Ivanhoe lode here passes through a thin albite-porphyry dike dipping west about 65° . The great Boulder lode passed through the same dike with local impoverishment at 2200 ft. When, however, the latter lode was encountered beneath the albite-porphyry dike it proved as rich as in upper levels, and the same result may reasonably be expected in Ivanhoe deeper levels. So far, then, as the evidence furnished by Kalgoorlie goes, it indicates that, so long as its lodes remain in quartz-dolerite, so long will they furnish ore equal in tenor to that found from the 500 to the 2000-ft. levels. The Horse-Shoe-Ivanhoe group of lodes may therefore be expected to carry ore to the 5500-ft. level, provided always that the quartz-dolerite dike persists, does not flatten in dip, and is not thrown

westward in depth by westerly dipping reversed faulting.

Archean strata, from the vicissitudes to which they have been subjected in the course of long geological ages, are normally much folded and distributed, while lode fissures in them are nearly vertical. It is a fundamental axiom in these older deposits that the nature of the lode wall exercises a vital influence on the richness and sometimes on the mineral character of the ore-body. Hence it rarely happens that a great depth is reached before the lode, worked from the outcrop downward, has passed out of the favorable rock. A notable exception is the Champion Reef of the Kolar goldfield, southern India, probably the richest single gold lode ever worked. From 3200 to 3800 ft. ore as rich as any obtained in the upper levels is now being worked and ore may be expected to persist in this fissure as long as it remains in the favorable hornblende-schist.

The greatest goldfield of the world, namely, the Witwatersrand, responsible for 37% of the world's gold production, is a pre-Cambrian goldfield, but the criteria of ordinary pre-Cambrian fields do not apply to it. Its deposits lie in sedimentary quartzites and conglomerates and are undoubtedly decreasing in tenor in depth. Having regard to all the geological conditions surrounding auriferous deposition on this field, it may be assumed that its gold was deposited relatively near the then existing surface and that deposition was due either to cooling on approach to the surface or to admixture with oxidizing waters, which in basin shaped sedimentary areas as those of the Witwatersrand, we know from analogy with artesian areas, may reach to depths of several thousand feet. The surface of most pre-Cambrian goldfields, on the other hand, has been subjected to erosion during a large portion of geological time, and the locus of gold deposition though now comparatively near the surface, was at the period of impregnation many thousands of feet below the then existing surface and beyond the reach of oxidizing waters, perhaps even beyond the influence of thermal changes.

Summary

Where auriferous orebodies have been deposited by the influence of meteoric oxidizing waters or by cooling on approach to the earth's surface, they may reasonably be expected to diminish in tenor with increasing depth and finally to disappear. The deposits to which this generalization appear to apply are those of the Tertiary andesitic group. Even for many of these, non-persistence of ore is more often a function of geological structure than of increase in depth. For all other deposits, and especially for those of the pre-Cambrian group, ore formed in strong well defined fissures may be expected to persist unchanged (apart from local horizontal variations) in 'depth', provided the rock of the lode walls is homogeneous and that the ore-bearing fissure does not pass out of that rock. In all these, therefore, geological structure and not 'depth' is the factor controlling the persistence of ore.

Air Agitation by Continuous Method

By DONALD F. IRWIN

In the majority of accounts which relate the performance of agitators, emphasis is laid upon theoretical conditions affecting power consumption or relative efficiency in causing units of pulp and solution to come into frequent contact, but the daily experience of working conditions is often lacking. As details of current practice may have interest for the sake of comparison, the following notes are submitted on continuous air-agitation in a battery of tall tanks at El Tigre, Sonora, during the past two and a half years.

The conditions for which this installation was designed were as follows: The treatment of 250 tons of ore daily, for a period of 48 hours; 80 to 90% of the ore, containing about equal parts of sand and slime, to pass a 200-mesh screen; the pulp undergoing agitation to have a consistence of 2.5 to 1, and treatment to be continuous.

In 1910 when this plant was designed, the Esperanza Mining Co., of El Oro, in Mexico, had just effected a notable success in continuous agitation by the use of Pachuca tanks, and their type of equipment is reflected in the plant at El Tigre, particularly in the manner of transfer of pulp from one tank to another. The accompanying sketch (Fig. 1) shows the pipe connections for that purpose.

Later installations have tended toward the surface catch-box type of pulp transfer from tank to tank, as first described in technical publications by Huntington Adams, of Natividad, but if conditions are closely watched, the submerged diagonal transfer pipe of the Esperanza type is quite satisfactory in operation.

This battery of agitators is equipped with the short, central air-lift columns described in 1910 by A. J. Yaeger, with

the exception of the last agitator. This one uses a full length column to save elevation in the discharge of pulp to the storage tank.

Operations began with the agitators piped as shown

in the full lines of the sketch (Fig. 2). Believing that pulp would flow freely in the connections, no operative difficulties were anticipated. However, trouble was first caused by imperfect classification, resulting in unduly sandy pulp for the agitators: sand began to settle in the piping between the tanks when the pulp was too thin, and this stopped the flow entirely in some cases. A supply of air at 80 lb. pressure was at once provided for, the piping of the by-pass system, and by manipulation of the three-way cocks, this high-pressure air could be admitted to any cock in either direction, forward or back, at will.

As the air-pressure was much greater than the re-

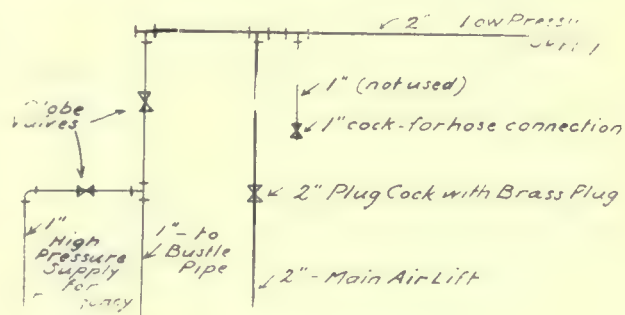

FIG. 2.

sistance of the pulp plus the head in the tank, it easily dislodged the sand when needed, and forced a passage for the stream of pulp, being sufficient to start the pulp washing through and to bring the level of the tanks to the proper height again. 'Blowing' of the three-way cocks is now rarely done, save to dislodge any waste, rags, or carpenter's rubbish that may have accidentally fallen into the stream of pulp and gotten past the chip-screens. Classification has been satisfactory for a long time past, and 'sanding up' is unknown.

After more than a year of uninterrupted operation of the agitators, decision was made to empty each one in succession and investigate the inside of the tanks, as it was suspected that sand had accumulated in them to some extent. When this was done, deposits of sediment was disclosed in several instances, which had seriously reduced the capacity of the tanks, and consequently the time of treatment of pulp. All the tanks so found had maintained the circulation of pulp by means of a small well or shaft through the body of the settled pulp. These mills were about 2 or 3 ft. in diameter, and were connected below with the foot of the central air-lift column. This sedimentation was apparently not governed by the sequence of tanks in the battery, as tanks No. 1 and 2 were nearly free from settled pulp, whereas it would be supposed that heavy particles would settle out at the first oppor-

tunity afforded them. The sketch (Fig. 3) shows the peculiar conditions found in tanks No. 4 and 5, and the step taken to prevent its recurrence. A crescent-shaped mass of slime and fine sand was banked up on the outer sides of these two tanks, while the opposite sides were fairly clean. Doubtless the current of pulp flowing through had cut across between the central air-lift column and the wall of the tank, leaving a dead area on the opposite side of the column where the pulp was free to settle. In order that the current might be directed straight through these two tanks, branching around both sides of the central columns as it had done in other tanks, the transfer pipe was flanged to the outer sides. This has served its purpose well, as shown by inspections of the tanks after six months service following the change; the tanks being found to be quite free from deposited slime and in no need of cleaning.

FIG. 3.

After the general overhauling referred to, an additional pipe for air supply, 1 in. diameter, was run down inside of each tank as far as the junction of the cone-bottom and the wall of the tank. At this point a circular ring of pipe was laid around the top of the cone and provided with eight $\frac{3}{8}$ -in. pipe nipples, 12 in. long, spaced at equal intervals around the ring. These pipe nipples were reduced to about $\frac{1}{8}$ in. at the tip, and were pointed downward and parallel to the side of the cone. This ring, or bustle pipe, is blown for two or three minutes on each tank twice every shift, and to this is attributed a part of the freedom from sedimentation during the past six months. There is no other air-pipe entering the tank save the air-lift supply pipe, nor is there any provision made for admitting solution under pressure through the air-lines, as is done in some plants where air-agitation equipment has been installed. High-pressure air may be admitted to the 5-in. discharge line, to which all the tanks are connected in common at the bottom of the cones. This is useful in case that tanks refuse to begin circulation with the use of the air-lift alone, but it is seldom needed. Operation conditions now admit of a much thicker pulp than was possible in the earlier days, and it is of great value as a preventive of sedimentation.

This group of agitators stands upon a combination concrete foundation and platform, with proper drainage launders leading to the sump of an air-lift which

returns any pulp or solution to the boot of the elevators that hoist pulp to the agitators. Such provision has been found to be valuable, and, in fact, indispensable, as the pulp under treatment is frequently subject to foaming. When this condition begins, large quantities of foam, or frothy pulp, are shoved out over the tops of the tanks and gather in the patio below. Ore of this character may suddenly start foaming when the level of the pulp in the tanks is near the top, and thus cause them to foam over excessively. If heavy tonnage-duty is required the pulp-level cannot be lowered, and until this is done the foam will continue to boil over, unless ore from different stopes is received. This foaming is aggravated by high protective alkalinity, but the chief cause for foaming lies in the ore itself; ore containing the largest proportion of slime causes the formation of more foam than quartzose ores. When pulp contains not more than two parts of solution to one of pulp, foaming is diminished, but the specific cause of the foaming is unknown. The solid concrete patio beneath the tanks serves as an emergency pulp-container or as a kind of safety valve, and the air-lift then will return the pulp to the tanks at the first opportunity. When running at or above the rated capacity, it is a common occurrence for a battery of agitators, connected for continuous agitation, to start foaming and sloping over in response to sudden increases in tonnage, or feed from the pulp-storage tank, and thus relieve the condition of the agitation battery. During periods when agitators have been running temporarily at a low level, I have occasionally observed clear foam on the surface of the pulp in the agitators over 50 in. deep.

Classification that will deliver pulp to the agitators for treatment with 80 to 90% passing 200 mesh, and a thickening of the pulp to 2.5 or 2 to 1, will do much to obviate the need of secondary air-equipment for starting up tanks after long periods of quiescence. These tanks call for little attention or adjustments by the solution men, occasional adjustments of the pulp level being almost the sole care required by the tanks themselves. The blowing of the bustle pipes is a part of the general routine, and does not take long—possibly about two and a half hours out of the twenty-four.

Air-compressing equipment for agitator service consists of a Sullivan Machinery Co.'s compressor, single-stage, duplex type, size 16 by 14 in., supplying 30 to 35 lb. air at the rate of 108 cu. ft. piston displacement per minute. Power is supplied to the compressor by an Allis-Chalmers motor of 100 hp., running at 490 r.p.m.; and an air-receiver, 4 by 12 ft., serves the usual purpose. Meter readings at the motor show the power supplied to be 88-90 hp., a rather higher figure than is sometimes quoted for this service. From this figure should be deducted the power consumed by the operation of eight air-lifts in the mill and cyanide plant, all of which are operated by this air-supply and all (save the one in the patio below the agitators) in constant

operation. To prorate the use of power accurately would be a tedious task, as all the air-lifts work under different conditions as to heads, tonnages, and thicknesses of pulp, but they doubtless consume as much power as one extra agitator. Therefore it appears that a fair estimate of the power required for agitation at this altitude, under conditions as described, is 9.7 to 10 electric horse-power per tank. This figure includes all power losses in motor, in compressor, and in transmission of air to tanks.

Local construction having been influenced by ideas and results achieved in the El Oro district, where the climate is mild or even hot, the consequence was that the cyanide plant was only partly enclosed, the agitators being without housing save the deck that covers them on top. Inasmuch as the winters in the Sierra Madre of Sonora occasionally have low temperatures with considerable snow and ice, it is now purposed to enclose the tanks to permit of successful heating of the pulp during agitation in cold weather, for investigations have shown that maintenance of heat in the pulp during treatment will be attended with a profit. Experimental work proved the inertness of the Na_2ZnCN_4 during cold weather, compared with its behavior during the warm months, and showed the necessity of warming the pulp in winter in order to secure the most satisfactory results.

Motor Truck Haulage

By F. L. SIZER

Below is the record of a Pierce-Arrow motor truck, No. 435, in service from June 18, 1913, to February 28, 1914, on the road between Willeox and the Mascot mine, a distance of $16\frac{1}{2}$ miles.

| | |
|--|---------|
| Total miles traveled | 6,462 |
| Gallons of gasoline used | 2,135 |
| Tons of ore hauled | 763.4 |
| Tons of merchandise hauled | 170 |
| Cost for labor and materials, per ton..... | \$2.90 |
| Cost per ton per mile | \$0.175 |

The ore was hauled from the mine to the railroad station at Willeox and the merchandise hauled on return trip to the mine, which is a continuous up-grade, there being a rise of 2200 ft. in the distance of $16\frac{1}{2}$ miles. There was considerable interruption of the haulage on account of bad roads in the rainy season during the summer and also in the winter. The mine is at such an altitude that the ice and snow makes it impossible at times to use even a motor car for two or three days at a time. Taken as a whole, the truck has given satisfaction when the climate and grades are taken into consideration. It is to be noted that there are grades of 23% on the road traveled.

The British Association, a well known society of scientists, will meet in Australia in 1915. It is hoped that Madame Curie will be one of the members of the party.

Mining in Manica, Portuguese East Africa

*The chief mining events in this territory in 1913 were the progress made on the Bragança mine belonging to the Andrada Mines Ltd. and the completion of the dredge for dredging the auriferous alluvials of the river Revue which has been built by the same Company. On the Bragança, another level, the 240-ft., has been opened and two winzes sunk from this to a depth of 100 and 70 ft. respectively with a view to opening another level at about 360 ft. The 120-ft. level has also been driven a considerable distance north. Development of the lode at depth is satisfactory. The output of this mine for the year amounted to 4891 oz. fine gold of which 355 oz. was in concentrate shipped. Preparations for dredging the Revue valley have been pushed ahead with the greatest energy during the past year. In the Inhamucarara valley, a new 1000-hp. electric power-station has been erected containing two hydro-electric units each consisting of a Pelton wheel and generator.

The 3-phase current is generated at 4500, transmitted at 15,000, and reduced to 450 volts for use on the dredge. Twelve kilometres of main line, and two kilometres of low-voltage line were erected. The new plant is connected with the existing Tristao plant of the same Company. The dredge, which was built by the Bucyrus company of the United States is 110 ft. long, carrying 71 buckets, of $7\frac{1}{2}$ cu. ft. capacity each, and designed to dig 25 ft. below water level, with a bank of 20 ft. above and, under favorable conditions, it should be able to handle up to 120,000 cu. yd. per month. Under normal conditions 450 hp. will be required. Regular dredging is now under way. In addition to the Bragança mine, two small properties produced gold regularly during the year, and the Guy Fawkes and four others produced small quantities of gold during various months in 1913. The production of gold considerably increased in 1913 as compared to the two previous years. This increase was due to the opening up of the Bragança mine. The output of gold for the territory was 5699 oz. fine gold.

Fortunately, throughout the year the labor supply has been fair, the health of the white workers has continued good, and that of the natives has been excellent, as in former years. This field continues to maintain itself very free from contagious diseases and no scurvy appears to exist on the field. The work of the geological survey which is being carried out under the direction of Wyndham Dunstan, director of the Imperial Institute, London, was again continued during the dry season of 1913. The region examined including the district of Sena and the greater portion of the Circumscription of Gorongosa. During the year a mineral survey map with explanatory notes and photographs was published in English, in pamphlet form, summarizing the results of the work of the geological survey in 1911 and 1912.

*Abstract from *The Beira Post*.

Progress at Chuquicamata

AN INTERVIEW WITH DANIEL GUGGENHEIM

The head of the A. S. & R. Co. was recently interviewed for the *New York Times*, with the following results:

The London newspapers, in reporting the recent annual meeting of the Exploration Company, quoted its Chairman and Managing Director as referring to the Chuquicamata mine as the greatest copper deposit in the world, and the *Industriale*, an Antofagasta newspaper, told of the plan now in progress for building a model city in the mountain desert, 9500 ft. above sea level. Mr. Guggenheim was asked if the statements thus made were accurate, and he confirmed them. Further details given by him in a matter-of-fact way show that the development is to be not only most extensive, but in several respects unique.

General Situation

The copper district, besides being up in the mountains, is 150 miles from the port of Antofagasta by rail. It is without a natural water supply, and water for mining operations and for the thousands of workmen who will be employed there is to be piped a distance of 40 miles. Although the Company owns rights for more than 30,000 hp. at a moderate distance from Chuquicamata, it has been found more advantageous to build a power plant at Tocopilla, on the coast where 53,000 hp. will be developed by means of an oil steam plant and transmitted 89 miles in the form of electric energy to the mining site in the mountains. This plant is to cost \$3,500,000. The first contract for oil, covering a period of years, will amount to \$10,000,000.

The extent of the deposit, 8000 ft., or more than a mile and a half, makes necessary the construction of railroad tracks in various directions, and this construction, together with electrolytic tanks, is part of the work now in progress. The preparations for the health, comfort, and convenience of the population to be transplanted to the district are thus described in the *Industriale*:

"With an astonishing rapidity, Chuquicamata is taking on the aspect of a great city of the future. The North American company, which is putting in very powerful installation, is busying itself at the same time in arranging all the conveniences possible for the thousands of workmen and employees which it must use in its operation. This is not done even in the very capital of the republic. Chuquicamata, indeed, will be the most healthful city of the country, and the cleanest; in fact, a city where its population has the greatest number of conveniences. The North Americans who will exploit Chuquicamata have undertaken a task which we do not hesitate to applaud. The buildings which are to be constructed for the many who will be employed in the workings of these mines constitute an example for other industrial enterprises. This Company will erect

in the city which is being formed the following buildings among others: A soldiers' barracks, two public schools, a Court House, a telegraph and postal building, a theatre, a hospital, a public quarantine, a Protestant Church, and a Catholic Church, a music hall for workmen, and a public library, and in all of these works large capital will be invested."

The Panama Canal establishment has been drawn on for both industrial and social welfare purposes, arrangements having been made to bring from the Isthmus some of the steam-shovels that have been used in digging the canal and sanitarians having been engaged to combat the same sort of conditions that have been overcome there. Incidentally, the Panama canal is one of the most important factors in making the deposits commercially available, as shipments can be made from Antofagasta, on the west coast of South America, direct to New York or London without going around Cape Horn or around the world. The Panama canal also affords a comparison by which an idea of the magnitude of the work to be done at Chuquicamata may be gauged. The known deposits are estimated by engineers at 200,000,000 tons of ore, to mine which a total yardage of earth must be removed, about 5,000,000 more than were removed in cutting the canal. It is estimated that the amount to be paid in wages to Chilean labor alone in getting out the known ore will reach \$225,000,000.

Discovery and Early Work

Mr. Guggenheim said that the existence of the deposits had been known for a great many years, but that owing to the natural difficulties and the need of large capital they were not regarded as available until recently, when they were bought by A. C. Burrage, who subsequently interested the Guggenheims. The deposits had been passed over time and again, after examination by engineers.

"The ore deposit," said Mr. Guggenheim, "is really a long hill, extending north and south 8000 ft. and the mineralized surface shows an average width of practically 1000 ft. The drillings show conclusively that the deposit is richer in copper at a depth than it is near the surface, and that the mineral is not found in veins, but is thoroughly disseminated through minute fractures in the rock so as to make a uniformly mineralized ore-body. Our engineers on the ground, who have made the drillings, tell us that tremendous as is the amount of ore already thoroughly developed, nevertheless only the minimum is known, and no one can make any calculations as to the maximum quantity of ore which may be extracted from this deposit, or as to the average value of the ore which has not yet been placed in sight, but which is absolutely certain to be developed by future work.

"While the underlying sulphide ores—that is, practically all of the ore below 400 ft. from the surface—can be treated in the customary way by water concentration and direct smelting, no steps are being taken at present to mine or treat any part of this lower sulphide deposit. All of the attention of the Company is being given to mining by steam-shovels the upper sulphate part of the deposit and to treat these sulphates by a simple and inexpensive process. For more than a year a demonstration plant has been working upon these ores, and it has been found from months of continuous operation that 90% of the copper can be extracted from them by means of the sulphuric acid obtained from the ore itself.

"More than 1500 men are working at the millsite and

many more at the coast power plant. The work is being pushed with such energy that the latest information from Chile is that the plant will be ready for operation by March 1, 1915. The plant now being erected has a capacity of 10,000 tons of ore per day, which will produce 120,000,000 lb. of copper per year, and it is expected that the actual production of copper will be begun soon after March 1, 1915, and that it will take a few months to get the plant up to its full capacity. Later an additional 10,000-ton plant will be added, as the coast power plant is more than sufficient to take care of 20,000 tons per day. To erect the second plant probably will take about eighteen months, so that before July 1, 1917, Chuquicamata should be producing at the rate of more than 240,000,000 lb. per year."

The Weidlein Leaching Process

For some time past E. R. Weidlein has been studying the application of leaching processes to the treatment of copper ores, working in the Mellon Research Laboratories of the University of Pittsburgh, under the auspices of the Metals Research Co., which is a subsidiary of the W. B. Thompson interests. Mr. Weidlein has devised a process, for which U. S. patent No. 1,089,096 was issued on March 3, and is now engaged in the construction of a small plant at Wabuska, Nevada, to test the process on a working scale under actual operating conditions. In the patent specifications the process is described as below.

The present invention relates to the recovery of copper in the wet way, from its ores, and is based generally upon the reversible reaction

More specifically, it contemplates a mode of operation which makes the utilization of this reaction of high commercial value, in that in actual practice the copper can be precipitated substantially quantitatively in the metallic form. This substantially complete precipitation is likewise accompanied with the regeneration of twice the amount of sulphuric acid necessary to dissolve out the same quantity of copper precipitated, so that the solution, while it is still hot, and after the copper has been precipitated out, may be used for re-leaching the original body of ore, or for leaching a new batch of ore, as the case may be.

In the preferred practice of the invention, the ore is leached, by percolation, or by agitation with or without the admission of air, with a 3.6% sulphuric acid solution. The free acid content of the copper sulphate solution thus obtained is lowered during the leaching operation to less than 1% of free sulphuric acid. The free acid is thereupon neutralized by adding the calculated amount of calcium carbonate or ordinary limestone, or, in fact, any alkaline substance. If the alkaline substance added is one which forms an insoluble sulphate, as is the case when calcium carbonate

is employed, the precipitated insoluble sulphate is separated by filtration or otherwise removed in any known way.

The copper sulphate solution will be neutral and will contain 1.5% copper, in which condition it is supplied to the absorption tower, of any suitable or convenient type. Sulphur dioxide (for instance, sulphur dioxide contained in smelter fume) will thereupon be pumped into the solution until the desired concentration of (1.5%) sulphur dioxide for the amount of copper in solution is obtained. The solution is then pumped to the precipitation tank or tanks, which may be made of iron, lead-lined throughout, and which are adapted to withstand, with safety, a relatively high pressure. Heat is then applied to the solution, in any suitable way, until a temperature of 150°C. is attained, giving a pressure of 100 lb. per square inch. As soon as these conditions of temperature and pressure are obtained, the pressure is released, the tanks emptied upon a filter, and the hot solution is run back on the ore for re-leaching purposes. The solution is very easily filtered, and the copper remains on the filter in a finely divided form. It may then be conveniently handled by melting and poling, or by compressing it to form anodes.

The typical example given embodies the conditions necessary for completing the reaction for the attainment of the best results. Thus, it has been found that the best results are obtained with 6% solution of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ (containing 1.5% copper) and under a pressure of about 100 lb. per square inch, at a temperature of about 150°C. It is commercially feasible, however, to increase the strength of the solution up to 3% metallic copper and to obtain a precipitation of approximately three-fourths of the copper.

The treatment of the solution, as it comes from the leaching tank, with an amount of calcium carbonate or other alkaline substance sufficient to neutralize the free acid, together with the conditions of temperature and pressure and of concentration of the sulphur di-

oxide in solution relatively to the concentration of copper in solution in the sulphate liquor, determine the nature of the precipitate which, under these conditions, closely approximates 100% finely divided metallic copper. The quantity of sulphur dioxide passed into the solution is determined by the degree of concentration of the copper, that is to say, the concentration of the sulphur dioxide solution expressed in per cent by weight should not materially exceed the concentration of the copper in solution expressed in the same terms. In this connection, it is to be carefully noted that solutions of copper sulphate stronger than 6% $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ may be, in part, precipitated by sulphur dioxide as metallic copper when the solution is first neutralized by the calcium carbonate or other neutralizing agent employed, but, in such case, the precipitation as metallic copper will not be complete. So also, at higher temperatures and pressures than 150°C . and 100 lb., complete precipitation of the copper in the solution may be obtained, but this precipitate will consist only partly of metallic copper and will contain, in large quantities, oxides, sulphites, and sulphides of copper; although sulphuric acid will nevertheless be regenerated under these conditions in sufficient quantity for re-leaching purposes.

The process is particularly applicable to the extraction of copper from low-grade copper ores, principally the carbonate, oxide, and basic sulphate ores. The sulphur dioxide may conveniently be obtained from smelter fumes, inasmuch as the percentage of sulphur dioxide in such fumes is normally sufficient to saturate a 6% $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ solution. Furthermore, the process finds a special application in connection with sulphide ores, inasmuch as the conversion of the sulphides usually occurring in such ores into the oxide by roasting will yield, in most cases, even more sulphur dioxide than is required for subsequent treatment of the solution. It may, therefore, be said that the process is applicable to all ores or other products containing copper, as, for instance, in addition to those above noted, to roasted matte from which the copper may be efficiently brought into solution by sulphuric acid. It is proposed to leach with the solution as it comes hot from the precipitation tanks, thereby utilizing its maximum leaching efficiency, and making the process continuous in the sense that the leaching solution is utilized over and over again for re-leaching the ore, after the copper has been precipitated each time out of the solution.

In order to maintain a constant volume of solution, the leaching is effected, as hereinbefore indicated, with a 3.6% sulphuric acid solution, assuming a chemical and mechanical loss in the leaching operation of about 25%. The precipitated copper is not contaminated with other metals more electro-positive, such as iron, as they will not be precipitated under the same conditions. The ferric iron present in the solution will use up some of the sulphur dioxide and convert it into sulphuric acid which will be an added advantage

to the process, and, at the same time, the reduced ferrous sulphate in the solution, when agitated with air, is an excellent leaching agent for copper.

It will be noted that the amount of copper precipitated, expressed in percentage by weight, corresponds, within certain limits, to the ratio of the amount of SO_2 employed to the amount of copper contained in the solution. For instance, if the solution contains 1.5% copper and the amount of SO_2 employed is 1.5%, then approximately 100% of the copper present will be precipitated as metallic copper. Or, if the same 1.5% copper solution contains 1% SO_2 , then approximately 66% of the copper present will be precipitated as metallic copper. If the percentage of SO_2 exceeds 1.5%, a complete precipitation of the 1.5% copper solution will be obtained, but will consist more or less of oxides, sulphites, and the like.

It will, of course, be understood that I do not claim broadly the use of sulphur dioxide as a precipitating agent in the treatment of copper sulphate solutions, inasmuch as the general reaction, as hereinbefore indicated, is well known, and its utilization, for commercial purposes, has been heretofore attempted. In every such attempt, however, in so far as I am aware, the precipitation of the copper in the metallic state substantially quantitatively has not even been approximated, and even its precipitation in the form of a mixture consisting largely of oxides and sulphites accompanied sometimes with a relatively small proportion of metallic copper has been incomplete. By the practice of the present invention, on the contrary, practically complete precipitation of all the copper in the solution may be obtained in the metallic form, by observing the conditions of temperature and pressure and of concentration of the sulphur dioxide solution relatively to the concentration of the copper in solution in the sulphate liquor, as hereinbefore specified; and, even with higher concentrations of copper in solution, and at higher temperatures and pressures, the preliminary neutralization of the free acid permits the complete precipitation of the copper partly in the metallic state. So also, with the employment of the preferred conditions of temperature and pressure hereinbefore specified, even though the concentration of the copper in solution may exceed the optimum, a much larger proportion of copper in the metallic form will be precipitated than is obtainable, in so far as I am aware, in the commercial practice of any other process based upon the employment of sulphur dioxide in the reversible reaction quoted.

By the term "substantially quantitatively" as used in the specification and claims is to be understood such a precipitation as will result in a residual leach liquor, which when used as a final wash-water, will leave associated with the spent ore an amount of copper so small that it shall not represent a material loss; that is, a loss whose maximum may be said to be one-fourth of the amount of copper originally present in the ore.

Blasting and Use of Explosives*

1. Powder magazines must be kept dry and well ventilated. Powderman in charge must keep magazine clean and free of litter of papers, sawdust, empty boxes, box covers, etc. All powdermen must observe and obey the special rules and instructions posted in the magazines relative to the storage, handling, thawing, and caring for explosives.

2. Separate magazines are provided. Dynamite and black powder must not be stored or kept in the same magazine. Blasting caps, electric fuses, and exploders must not be stored with dynamite and black powder.

3. Open or exposed lights positively must not be used in or around magazines or fuse and cap houses.

4. Smoking is positively prohibited in or around magazines or fuse house, or in or around the pit or mine workings where explosives are being conveyed or are being used.

5. Employees must not slide or handle roughly or carelessly cases of dynamite or other explosives, either in magazines, in wagon transportation, or in and around the mine workings.

6. Blasters and their helpers and all employees engaged in the handling of explosives must not wear hob-nailed shoes. Shoes with soles studded with hob-nails, or other heavy nails, or with metal toe or heel plates may be a source of danger and must not be worn.

7. The accumulation of an excessive quantity of explosives at or near a hole is prohibited. The necessary supply of powder for one or more bore-holes prepared for loading must not be delivered within 50 ft. of the nearest hole. From this temporary supply, powder must be carried to bore-hole only in such quantity as can be rapidly loaded, so that at no time during the charging of a hole will there be more than 150 or 200 lb. of powder in the immediate vicinity of or at the collar of the hole.

8. Blasters must protect their field supply of explosives. Canvas tarpaulins, asbestos or fireproofed coverings are furnished by the Company and must be used by blasters to protect their supply of powder from dampness and the possible danger of flying sparks and flying rocks and débris from blasts.

9. The use of frozen or chilled explosives is positively prohibited. Blasters must not cut or break a frozen stick or cartridge of dynamite.

10. Iron or steel bars or tools for tamping must not be used. Use only a wooden tamping stick with no metal parts.

11. Packages of explosives must not be opened with a nail-puller, chisel, pick, shovel, or other steel or iron tool. Employees must use hardwood wedge and mallet provided for this purpose.

12. After 'springing' a hole, that is, exploding a

charge to chamber a bore-hole, blasters must wait at least an hour, or until the bore-hole is cool, or has been cooled by a deluge of water, before loading charge to blast.

13. A primer (a cartridge of dynamite with blasting cap and fuse, or an electric fuse attached) must not be forced into a bore-hole.

14. The regulation crew for loading bore-holes shall be and consist of not more than 4 men, the blaster in charge with three helpers. At no time shall there be more than four men allowed at or around a bore-hole when same is being loaded or charged.

15. Employees, other than blaster and his regular helpers, are positively prohibited from approaching closer than 50 ft. of a bore-hole when same is being charged with explosives. Employees or other person or persons violating this rule do so at their own risk.

16. Blasting caps, electric fuses, and miner's or safety fuses with detonators attached must not be carried or conveyed around the pit or mine workings with dynamite or black powder.

17. Blasting caps, electric fuses, and safety fuses with caps attached must not be carried by employees in their pockets.

18. Electric blasting apparatus must be frequently tested, and must not be used unless in good repair, and all leading wires and electric fuse wires, etc., must be in perfect condition. Do not use old, damaged electric fuse or connecting wire.

19. For bank blasting, electric fuses with insulated copper fuse wires less than 30 ft. long must not be used.

20. Safety fuses for use in bull-dozing or top blasting must be prepared in fuse magazine. Blasting caps or detonators must be securely and properly crimped upon the fuse.

21. Safety fuses, cut and prepared in the fuse house for regular blasting operations, must not be less than 24 inches in length.

22. The use of a fuse less than 24 in. long is positively prohibited. Powdermen and blasters must not cut fuses short to save time or for any other purpose.

23. In bull-dozing or dobie blasting, blasters must not light or fire more than 20 charges or shots at one time.

24. In dobie blasting, when a piece or length of safety fuse is used to spit or light a number of charges to be fired, blasters must see to it that the fuse so used has no cap attached. The use of a fuse with blasting cap attached for a 'spitter' is positively prohibited.

25. In firing two or more charges, no two fuses should cross each other.

26. The free end of safety fuse must be slit and turned sideways to expose the powder train or core without spilling out the powder so that the fuse can be readily and quickly lighted.

27. When blasting is to be done after regular shift hours, powdermen and blasters must always wait 10 minutes after dismissing the shift before firing shots.

*From the book of 'Rules and Regulations' of the Nevada Consolidated Copper Company.

The Ching Hsing Coal Basin

By EDWARD DI VILLI

The Ching Hsing coal basin is one of a series of bituminous coal basins in western Chihli province, north China, at about 114°E and 38°N, skirting the foothills which border the flat flood plain of the Yellow river. To the west are the well known and extensive anthracite deposits of Shansi province, while to the north and south are other coal deposits extending south to N 35° 15' and north 40° 50'. These deposits must not be confused with those worked by the Chinese Engineering & Mining Co., and the Lanchow M. Co., which are near Tongshan, in the same province but northeast of Tientsin.

A competent mining engineer has given the following section through a part of the Ching Hsing coal field:

| | Feet. | | Feet. |
|--------------------------|-------|--------------------------|-------|
| Loess | 46 | Fine grained basalt..... | ½ |
| Argillaceous shale | 2 | Baked coal | 3 |
| Arenaceous shale | 2 | Marl | 3 |
| Argillaceous shale | 3 | Arenaceous shale | 3 |
| Yellow sandstone | 3 | Dark arenaceous shale .. | 3 |
| Compact sandstone | 12 | White slate | 3 |
| Marl | 12 | Calcareous shale | 3 |
| Marl | 4 | Light indurated clay.... | 3 |
| Carbonaceous shale | ½ | Clay-slate | 3 |
| Coal | 1½ | Coal | 28 |
| Arenaceous shale | 8 | Coal | 1½ |

These last dimensions are in Chinese feet = 1⅓ English feet.

The Chü Yang Hsien coal field is situated 60 miles north of the Ching Hsing coal field. The geolo-

FIG. 1. SUPPOSED CROSS-SECTION AT CHING HSING.

My own observations were made in different workings and the geological section as below:

gical age and mode of occurrence are the same for both fields. The area of the coal fields is about 10 square

FIG 2. BLOCK FAULTING AT CHING HSING. THE COAL IN THE BLOCK TO THE LEFT IS 120, THAT IN THE MIDDLE IS 160, AND THAT AT THE RIGHT IS 280 FT. BELOW THE SURFACE.

Geology of the Basin

The geological horizon in any direction for several miles is of Carboniferous age and I was able to obtain reliable paleontologic evidence to confirm this opinion. The ground is formed into a series of square plateaus by step-faults, intersecting each other at right angles, and having north-south and east-west trends. The earlier and greater faults run east-west. The later ones are more numerous and have a lesser throw. The result of this system of faulting is that there are certain areas in which it is unprofitable to mine. The depth from the surface to the coal varies from 120 ft., 157 ft., 180 ft., 280 ft., up to 400 ft. That the north-south faults are of recent geological age is shown by the unworn edges of the fault scarps, sometimes as much as 100 ft. high, but more often only 5 or 10 ft. high. The slickensides are not mineralized, but some very pretty crystals have been extracted from the slickensides of the east-west system of faults.

The following log shows the thickness of the strata passed through in sinking a shaft at Hsi Kou:

miles with some smaller detached areas to the north and east. A typical section through the strata is as follows:

| | Feet. | | Feet. |
|-------------------------------------|-------|---|-------|
| Loess, clay, sandstone, slate | 300 | Sandstones and shales.. | 5 |
| Coal (very poor and stony) | 1½ | Coal, No. 3..... | 10 |
| Slate, sandstone | 100 | Sandstones and shales.. | 5 |
| Coal, No. 1..... | 4 | Coal, No. 4..... | 12 |
| Sandstones and shales.. | 3½ | Limestone, sandstones, and shales | |
| Coal, No. 2. | 7 | Coal | |
| | | Limestone | |

The Chinese work these coal mines in a primitive manner and solely to meet the local demand for pottery making. Shafts have been put down everywhere and abandoned. Flooding is a problem with which they do not care much to grapple. The work seems to go on in a haphazard manner with nobody in command. If you go down a shaft you will be let down in a very dilapidated and dirty basket, and if you are inclined to be at all nervous don't examine the ropes. That can always be done afterward, it provides food for

reflection. No consideration has been given for the comfort and convenience of the coolies. Ventilation is a problem that has ever troubled Chinese mining engineers. Fatal underground explosions are not at all of rare occurrence. In fact, everywhere you will find evidence of the Celestial total disregard for the value of human life. Nevertheless the Chinese always manage to extract handsome profits from their mining ventures. With their primitive methods they have carried out some truly wonderful work. Eliminate the 'hanger-on' system and I would sooner work with the Chinese than with any other man on earth.

Concreting the Junction Shaft of the Calumet & Arizona

*This is one of the main shafts of the Superior & Pittsburg portion of this property at Warren, Cochise county, Arizona. It is a splendid piece of work and was finally finished February 8, when the putting in of the guides and cleaning of shaft was completed. The work was commenced December 2, 1912, and the actual working time on the job was 295 days. The shaft has five compartments, 6 by 27 $\frac{1}{4}$ ft., and is concreted to the bottom, a depth of 1535 ft. below surface, the first forms being placed in position there, and work being upward from this point. Concrete was sent down the shaft by a 4-in. pipe, the material being delivered to an iron bucket in which was a bottom of wood, and leading from which was a distributing pipe which could be directed to any point in the forms desired to be filled. This method worked without any hitch and progress was rapid. When the 1535 ft. was completed, work was started at the bottom of the shaft, on the 1800-ft. level, and brought up to connect with the concrete above. All divisions in the shaft were concreted, and the pump stations at the 1000 and 1500-ft. levels were made fire proof by putting in concrete floors and plastering the walls. There was 6530 sq. ft. of flooring in the 1000-ft. station. Guides in the shaft were bolted to the walls, holes being drilled through the concrete and timbers.

The concrete walls of this shaft are from 8 to over 24 in. thick. In places where there were openings behind the shaft that were not too large they were completely filled with the concrete. There were no bearers put in the shaft, as these wall inequalities when filled with the concrete made them unnecessary. It was found that it was about as cheap to fill the moderate-sized openings back of the shaft with concrete as with waste, the cost of the concrete poured being about \$4.50 per yard. In places where openings were particularly large, waste rock was used. Through the central portion of the shaft is a break piece of ground, an old water course filled with water-worn boulders and where trouble could be looked for if it came in any portion of the shaft. Extra precautions were observed here in making the shaft as strong as possible. The

shaft is a fine one, not a half inch out of line for its entire length, and cages go through it smoothly.

The cost of concreting this shaft was about \$200,000, the top 1535 ft. requiring an expenditure of \$164,701. The cost of wooden forms was \$5160; cost of the pipe through which the concrete was fed, \$1443; and storage bins, \$7500. The work also included the concreting of the ore-pocket at the 1400-ft. level. There was a complete plant at the mouth of the shaft for crushing, mixing, and handling the materials. The limestone with which the cement was mixed came from the Company's quarry near by. The sand was obtained at Fairbanks. All of this, with the storage bins, etc., has been removed and there is nothing about to indicate that such an important job was done. Eight men were employed per shift, three shifts worked per day and for seven days in the week.

Determination of Sulphur in Pyrite

A new method for the determination of sulphur in pyrite has been described by Ernest Martin in *Mon. Sci.*, and an abstract is given in *Chemical Abstracts*. The method is as follows:

Treat $\frac{1}{2}$ gm. of finely ground pyrite in a 150-c.c. flask with 25 c.c. aqua regia (equal parts HCl and HNO₃) prepared a few minutes in advance. Allow to act several hours (preferably over night) in the cold, add about 1 gm. NaCl, evaporate almost to dryness on a sand bath, take up with 2 c.c. HCl and sufficient water, then add 50 c.c. boiling water and little by little 4 gm. Na₂CO₃. The precipitate is not bulky and does not retain sulphates when washed with boiling water. To the filtrate add two drops methyl orange (0.1%) and neutralize exactly (rose tint) with HCl. Boil off CO₂, add 60 c.c. of Ba(OH)₂ (45 gm. per litre) and a drop of phenolphthalein. Pass CO₂ (carefully washed), stopping the flow of gas the moment the rose color just disappears. Filter, wash with hot but not boiling water, cool, and titrate with 0.5 N HCl to a rose color. Multiply the c.c. HCl used by 0.008 to find the S in the sample, or by 1.6 to find the percentage. To determine S in burned pyrite, weigh out 3 gm. and proceed as before, but use 8 gm. NaCO₃ and 25 c.c. Ba OH. To determine Pb, Cu, and Zn in pyrite, mix 3 gm. in a porcelain crucible with 2 gm. S and 8 gm. KNaCO₃, cover with a little Na₂CO₃, put the lid on the crucible and fuse for 15 minutes. Extract the cooled mass with 300 to 400 c.c. of hot water, add 20 c.c. HCl (22°B.), allow to digest several hours, remove, and wash the crucible. Add 25 gm. crystals sodium acetate, allow to settle, filter, and wash with H₂S-water containing sodium acetate. Separate the ZnS by dissolving in HCl, precipitate as ZnS and weigh as ZnO. Burn the filter + CuS + PbS in a porcelain crucible, dissolve in HNO₃ and electrolyze, or, if preferred, separate the Pb as PbSO₄.

Bank clearings in the United Kingdom in 1913 totaled \$79,987,760 065.

*Abstract of an article by George A. Newett in *Iron Ore*.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Some Unwritten Cyanide History

The Editor:

Sir—Decision of the suit for infringement by the Tonopah Mining Co. of the Brown patents removes one threat of pestiferous litigation from the field of metallurgy. It also recalls a bit of history which may interest others. In the years 1900 to 1903 I was associated with mining companies in Colorado, with some of which Alden H. Brown, the patentee in the suit concerned, was also connected. Mr. Brown is a graduate of the State University of Iowa. After service in the engineering corps of the Burlington, Cedar Rapids & Northern railway, he came to Boulder county, Colorado, about 1898, and, in connection with J. C. Beeler, a prominent contractor and quarryman at Cedar Rapids, Iowa, purchased, worked, and shortly sold at a good profit, the Longfellow mine. Later he took the management of the Wano Mining & Milling Co., which owned a property near Jamestown, also in Boulder county. The ore contained gold, partly in the form of tellurides and partly finely divided and intimately associated with metallic sulphides. One of the officers of the Wano company was James G. Berryhill, of Des Moines, now vice-president of the Nevada Douglas Copper Co. Mr. Berryhill was at the same time the principal stockholder in companies operating at Idaho Springs and Cripple Creek, upon whose staffs I was then serving. Mr. Berryhill learned in Chicago of the work done at Mystic, South Dakota, by Frederick H. Long, and visited the plant. Being impressed with the results Mr. Long was obtaining in the treatment of the so-called 'blue ores' of the Black Hills, he sent me to make preliminary tests and investigate the process. This was in the summer of 1901. It will be remembered that this was when cyanidation had progressed only to the point of leaching relatively coarse sand and when chlorination was still the dominant process at Cripple Creek. Mr. Long, however, was grinding his ore fine, 'all-sliming' we have since learned to call it, was agitating his solutions with an air jet much as is now done with a Pachuca vat, except that the apparatus was smaller and the circulation was down through the vat and up through an outside pipe, and he had developed a filter, which depended upon a water pressure to wash the cake and which filtered excellently though it was out of commission for hours afterward while the cake was being removed by hand. Mr. Long was attempting to treat ore by chlorination, developing the chlorine by electrolysis in the solution while it was being circulated

in a closed apparatus not greatly unlike the agitator already described. Incidentally, cyanide was added to the solution, but the main reliance was upon the chlorine.

Preliminary tests being favorable, arrangements were made for a thorough trial, running upon ore from the Wano and from the Hull City or Independence Consolidated at Cripple Creek. Samuel Newhouse and Messrs. W. P. Dunham and Eben Smith joined in having the tests made. A. J. Bettles represented Mr. Newhouse, W. C. Oates came from Philip Argall's staff to represent Dunham and Smith, Mr. Brown looked after the interest of the Wano company, and I represented Mr. Berryhill. With the enthusiasm of youth and lacking somewhat the experience of years, I recommended a large-scale test. In the consultation of the principles at Denver this grew until several carloads of Cripple Creek ore were shipped to Mystic, as well as one car from the Wano. Mr. Brown and I went ahead to organize the staff for the mill test, he acting as assayer. When the ore arrived, a car was unloaded and work began. The first difficulty involved was the fine grinding of so large a quantity. It was before tube-mills had penetrated beyond cement manufacture and the apparatus used was a Kent mill. It did the work, but at large cost for repairs. Eventually the Wano ore was pulverized, and, the others having arrived, a test was run. It resulted in an extraction of 65 in place of the expected 90%. A subsequent test on the Cripple Creek ore gave about the same result. After the first trial the use of salt and the electric current was discontinued, and straight cyanidation was done. While it was found impossible to raise the extraction, surprisingly quick results were obtained. My recollection is that on the Wano ore as much gold went into solution with sliming and air agitation in 15 minutes, as Mr. Brown had been able previously to dissolve in five days' leaching. This fact and the filter impressed all of us, but the main result claimed, decomposition of the tellurides, having failed to materialize, further work was abandoned. I recall that in studying the tailing from one of the tests, Mr. Brown suggested that the coarse gold and that associated with the sulphides could be saved by simple concentration following cyanidation. Doubtless this was the germ of the idea that he later worked out in practice at Jamestown and patented. The patents, passing into other hands, became the basis of the speculative lawsuit just decided.

The little group that worked together those pleasant summer days is widely scattered. Bettles is dead and his great mill at Bingham has been rebuilt; Oates has gone, I know not where; Brown turned his attention to Cuban iron ores and has done well; Long is in Chicago, and, I believe, applied his filter to other uses; and I now work with pen and paper in place of sampling cloth and notebook. It was a congenial circle and the work itself most interesting. Not far away, C. W. Merrill was then working on the slime press

he later perfected. Still nearer, J. V. N. Dorr was perfecting the Moore filter and developing the other processes and devices that are now being so widely adopted. At Mystic, with the value of all sliming demonstrated, with air agitation in use, and with a workable if imperfect pressure filter, we let slip the chance to make the Black Hills notable for other of the more important inventions that through cyanidation have let loose on the world a flood of gold.

H. FOSTER BAIN.

San Francisco, March 25.

Prospecting and Government Aid

The Editor:

Sir—I had some experience in British Columbia last winter which I think should interest those who have been discussing how the Government can help the prospector and mining companies.

I was working for the British Columbia Copper Co. in connection with a big diamond-drill job near Princeton. Charles Camsell was district geologist of the Canadian Geological Survey. He had been there and written a paper based on the work done there several years previous. With the accumulating data that the British Columbia company was gathering, he was enabled to correct and modify original ideas. He made frequent trips to the camp to keep in touch with new data. He did not bring a staff with him, but came alone. Before leaving, he would express opinions and give ideas and then write them up at headquarters. He made the rounds of all the mining properties in his district with some regularity, and was familiar with geological conditions prevailing in that region because he visited so many properties. Most of them were prospects. It must be remembered that we were developing by drill-holes mainly, and that the mines had never made any shipments, and that there was no assurance that there ever would be any at that time. The fact that the Company was spending a large sum every month in that district made the Canadian Geological Survey feel that they should give us the benefit of a geological expert who would do all he could to guide us. This meant that he frequently expressed an opinion instead of a demonstrated generality, and you could take it as an opinion or leave it. I think these reports on that whole district were as practical and helpful as any geological studies could be. They were intended to bear directly on our problem. They were not expensive. There were no elaborate preliminary topographical maps.

The points that impressed me were: (1) that by constantly making the rounds of one district, the district geologist becomes more familiar with the conditions in his territory; (2) that examinations were frequent; (3) that they were inexpensive; (4) that almost any prospector could get information from a well qualified government geologist by doing work on his ground; (5) that the geologist in his examination, and also in his reports, would take the chance of drawing a con-

clusion like any other mining engineer has to do, and not confining his report to what is already known; (6) that these papers appeared in print promptly.

I examined one prospect owned by two men who worked on it conscientiously. They had a good road built part way and a trail the balance of the way. The Government had built that road the previous year. They applied to the road supervisor for a road. He actually looked over their ground to see that it was not a fraud. Being satisfied, he spent \$200 that year on a road to a prospect that had not shipped a pound of ore. The Government must have spent at least \$20,000 on the road from Princeton to the British Columbia company's drilling ground before the tonnage was developed and, therefore, at a time when help was most needed.

Now it has been my experience that as far as metal mines are concerned, our United States Geological Survey does not come into the district until its reputation has been established, which is when you need it least. Like most American mining engineers, I am proud of our Geological Survey and the splendid personnel, but I do wish they would get in the same touch with us that they did in Canada. I am beginning to believe that our Survey would do better in covering more ground and by not going into such minute details about matters that are inconsequential, and going over the ground oftener. I recently made an examination in the Eureka, Nevada, district. The Geological Survey reports are classics that date back to Clarence King in the early eighties. Since then a great deal of work has been done, and these old reports are not now worth much. They go into great detail about fossils and correlation of strata. If the geological work had been confined solely to economic considerations and geologists had been going in there at regular intervals, the whole job would not have cost any more and there would be some modern ideas on the files. There is no use making a most detailed academic report on a camp at a time when it is booming and everybody has plenty of ore and then leaving the poor thing neglected for 30 years. Eureka is by no means a 'dead one.' A few kind words from the Survey today, based on a comparatively inexpensive examination of present conditions, might do more good than all the reports made 30 years ago.

I should like to see the district geologist in our Western states making his rounds continually and reporting annually on the geological progress and laying stress on published ideas that have been disproved or new theories that the companies are trying out. Such a district geologist would not need to be a first-class man. Through association with the managers in his district he would get into much closer touch with the needs of his district, and might get to that stage after a while where he could make a report without telling how many millimetres in length are the various feldspar crystals. Occasionally the enormous appetite of the Survey for this sort of stuff could be

satisfied by sending in a 'regular' geologist.

There are many obscure camps which could be made successful by the solution of some geological problem, but the operators do not know enough about geology to even know their own needs or recognize the solubility of their own problem. The Survey will overlook that camp until it has a reputation, which might never be. The district geologist, acting as a scout, would not overlook it and would bring it to the attention of his superiors, with the possible development of a new camp. When a camp is prosperous the Survey comes in with both feet, but when a camp is on the wane and ore is getting scarce, and we need the geological data like a sick man needs a doctor, that is just the time they 'shake' us and leave us high and dry with data that are ancient history. I have made examinations in several camps which the Survey had not visited for the last eight years and which were by no means decadent.

I think the Survey will work in closer touch with us as time goes on, and the point I want to make is that I think we can learn something from Canada in this respect, though I do not like to admit it.

F. SOMMER SCHMIDT.

Salt Lake City, March 9.

Prospecting and Leasing

The Editor:

Sir—I have read with interest the discussion relative to prospecting, and am glad to note the consensus of opinion regarding the ways in which prospecting may be aided and the unanimity of opinion against any direct government aid. There is one point which it seems to me has not been brought out as clearly and emphatically as it warrants. The greatest handicap to prospecting is that under the present laws the prospector is virtually confined to the unexplored regions, and these are no longer where they used to be.

For as soon as a find of any consequence is made, the world rushes in and patents all ground in the whole region, forcing the prospector back into the wilderness, where a find to be worth attention must be of exceptional value. While it is true that some of these claims are dropped after the collapse of the boom, it is done gradually and it is difficult for the man in the field to discover what is open and what is held. If claims were leased instead of being patented, and reverted to the Government when the holder ceased to take further interest in it, the prospector could always know in the field the ground upon which he could pursue his calling, and this he would still be able to do close to transportation, in many cases even in the midst of a producing district, where capital would be most willing to support his efforts and where anything found would have a value. Under such conditions there would also be less likelihood of camps being abandoned while yet there was much undiscovered mineral in them.

R. W. BROCK.

Ottawa, Canada, February 9.

Ore

The Editor:

Sir—Ore is metal-bearing rock; no more and no less. I find an outcrop of ore; by hard work and living on straight beans and jackrabbit, I manage to make expenses or a little more. Along comes T. A. Rickard, and I take a liking to him at once; we go into partnership.

Mr. Rickard by adding tomatoes and canned salmon to our bill of fare, at once turns my ore into waste, and we have our first squabble. By cutting down expenses and working harder, we manage to break exactly even at the month end, and I take a day off washing clothes in the wheelbarrow, while my partner fossicks around for a new word.

We keep digging, put up a whim, and hire a few miners; my partner doing the assorting, which he does into four piles: (1) ore, (2) probable ore, (3) possible ore, and (4) waste. I entreat him to call the hole a mine, as we have to use candles, and the windlass days are over. He insists that it is still a prospect, and we call on the cook as judge. He tells us that if we will both casually fall down the hole, he will be able to form an opinion; that if we break our necks it is a mine, if not then it is only a prospect. Things rock along in this way for some time, when my partner, after balancing up the books, comes over to the boarding house and addresses us in this way: "I am sorry men, but you are not miners at all, you are all 'muckers'; I find that the 'ahem' is not paying expenses." Then one of us quietly closes the door and we surround him and we all talk at once. We tell him that a mine is an excavation where ore is extracted; that the other fellow's hole may or may not be, but one's own is a mine every time; that a definition or a word, to have place in our language, must stand the test both of time and place; that we do not use 'Gadzooks' today, nor will we use 'piffle' tomorrow; that ore is ore just as sure as eggs is eggs and it makes no difference if the rancher who raises them does go broke at it. Mr. Rickard admits his mistake (there were 12 of us), and to play safe I will not sign my name.

Nacozari, February 9.

VENTURESOME.

New topographic maps, 16½ by 20 in., recently published by the U. S. Geological Survey, are as follows: Holt quadrangle, San Joaquin county, California; Marysville, Butte, and vicinity, embracing parts of Butte, Colusa, and Sutter counties, California; Red Mesa, in La Plata county, Colorado; Slug creek, embracing parts of Bannock and Bear Lake counties, Idaho; Stockton, San Joaquin county, California; and Woodland island, including parts of Contra Costa and San Joaquin counties, California. The price is 10c. each, or \$3 for 50.

Fifty tons of metallic tin was produced in the United States in 1913. This came from three places in Alaska, one in South Dakota, and one in South Carolina.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The foundry of the Mysore mine, India, produced 395 tons of castings in 1913.

St. Louis is now building a filtration plant to handle 160,000,000 gal. of water per day. When completed it will be the largest rapid sand filter in the world.

Mule traction is being used on No. 10 level of the Tonopah Belmont mine. The animal hauls three cars of 1900 lb. each trip, and lessens tramming costs.

Consumption of chemicals at the Nundydroog cyanide plant, India, during 1913, was as follows: cyanide, 0.557; zinc, 0.075; caustic soda, 0.180; and lime, 0.542 lb. per ton.

Flotation at the Lloyd copper mine, New South Wales, is doing good work. Before treatment the tailing averages 1.3%, and the residue 0.25% copper, a recovery of about 81 per cent.

Transporting wire rope to inaccessible points is often necessary. In the state of Puebla a track cable weighing 29,000 lb. was carried to a mountain top in connecting coils of about 100 lb. each, by an army of peons. When mules are employed about 220 lb. weight is allowed to each mule.

Crushing equipment for a simple gold ore may not extend beyond rock breakers and stamps; but the best results from leaching practice are generally obtained when a large percentage of the sand passes 60-mesh screens. There are, of course, instances where a coarsely crushed product can be leached with economic success; but such cases are exceptional and comprise instances where the ore is usually porous. With a normally hard ore, comparatively fine crushing is essential to success, and the stamp-mill is not altogether suitable for the purpose. The practice of following stamp-mill crushing with regrinding in tube-mills is generally adopted as an alternative scheme. A tube-mill is, however, essentially a sliming machine, and two disadvantages accrue from its use in this connection. Amalgamation after tube-milling does not recover the percentage of gold obtainable after single crushing by stamps, and more slime is made than by the alternative method of reduction. Increase in slime production often means an increase in cost of treatment in excess of the increased recovery. Power consumption, especially where coarse mine rock is used in the tubes, and where comparatively large tonnages of chippings and gravel from the 'pebbles' have to be ground to the same mesh as the final product to be cyanided, is out of all proportion to the work done. On the other hand,

fine crushing in a stamp-mill, that is beyond 30-mesh screens, involves insurmountable difficulties in screening and discharge. The latter operation can be only partly successful and is unsatisfactory when fine screens are used. Besides, there is constant trouble due to impact of coarse rock and jar on the fine mesh wire which results in frequent breakages of the screens and consequent loss of time. As a suggestion toward obviating these disadvantages, in single crushing to beyond 30 mesh, the use of the wet-crushing ball-mill may be mentioned. In the latter case, the screens, of what-

SECTION OF A KRUPP WET BALL-MILL. PARTS AS FOLLOWS:

ever mesh, are kept free and clean by a constant reverse spray of water through the screening and into the mill. The fact that the screening is, in addition, constantly passing through a water-bath is also an advantage. There is no danger of breakage of the screens except as the result of direct wear, and even the latter is minimized. The ground pulp is screened automatically through coarse punched screening before going to the fine screens, the oversize being returned to the centre of the mill for regrinding. Hence only fine material comes into contact with the fine screens. An additional advantage also results with regard to amalgamation, and lies in the fact that the classifying action of the mill allows of the immediate discharge of the amalgamable gold as soon as it can pass the outer screening. Unnecessary 'hammering' is therefore avoided, and a higher amalgamation efficiency obtained.

Special Correspondence

JOPLIN, MISSOURI

GRANBY MINING & SMELTING CO. STARTS SECOND FIFTY-YEAR LAP.—PREPARE TO FIGHT HEAVY WATER IN SHEET-ORE DISTRICT.—ZINC AND LEAD NOTES.

The oldest mining company in the Missouri-Kansas-Oklahoma district is the Granby Mining & Smelting Co., which has just completed a corporate existence of 50 years. The Company began work when only galena was mined commercially, zinc ore, known as 'jack,' being discarded as worthless. At a meeting of directors of the Company in St. Louis, holders of 19,684 out of a capital stock of 20,000 shares voted unanimously authorizing the officers to continue the life of the Company. Five directors of the Company were elected as follows: Norris B. Gregg, J. H. Grover, H. O. Edmonds, Kennett Burns, and Elias S. Gatch. The Company's first mining was at Granby, Missouri, where several hundred acres had been purchased. A small lead smelter was operated there before the war. During the Civil War the rival armies alternated in the possession of the lead smelter. Today the Granby company has nearly 30,000 acres, much of which has been proved to be mineralized. A lead smelter is operated at Granby, and a zinc smelter of 3760 retorts at Neodesha, Kansas. A new zinc smelter of 3240 retorts will be completed at East St. Louis this year. In addition to operating its smelters and several large mines, the Company also does a leasing business, and scores of producing mines are operated on its various tracts.

An electrically belt-driven pump, of centrifugal design, with a capacity of 1500 gal. per minute, has been installed as an emergency pump at the North Webb City, Missouri, central pumping plant, which drains the bulk of water from that field. Expectation of heavy spring rains caused operators to make the addition. The North Webb City plant is the largest ever operated in that field. At the present time three pumps are kept going continuously, throwing 1800 gal. per minute. These consist of two centrifugals and one steam pump. There is also an extra 5-in. steam pump for emergency. Water is lowered to 210 ft., above which level all the mining is done. The ore carries from 1 to 3% blende and galena, the former predominating. Operators of the various mines affected by the pumping contribute toward its upkeep.

Homer Sewall, representing Ohio capitalists, paid \$35,000 for first lease on 120 acres of the Sheridan-Adams Royalty Syndicate property at Thoms Station, the lease being held by the Coats & Ortt Mining Co. Two concentrating plants are in operation on the property, one, the Coats & Ortt mill, having recently made an unusually good showing. The other is the Vinegar Hill mill, operated by the Hardy Mining Co. This has been a steady producer for more than a year. Prior to about a month ago, the ore at the Coats & Ortt mine was low grade. Operations were extended to deeper ground, the result being an improvement in the concentrate, which now runs close to 60% metallic zinc.

Deeper work is being done at the Little Mary mine, operated by T. F. Lennan and associates, northwest of the Neck City, Missouri, camp. The ground is so soft that timbers have to be set almost touching each other and spiling has to be driven ahead of the heading; but the richness of the orebody coupled with the high grade of the cleaned concentrate makes this soft-ground mining attractive. The Little Mary ranks as one of the longest lived producers of the north part of the district. Operators have faced several handicaps, such as caving ground. At one time the ground caved in beneath a creek that flows across a portion of

the lease and the mine was flooded. Months of steady pumping were required to drain the ground, while a new channel had to be dug for the creek. The new work is being conducted from a shaft, just completed, which was sunk to a depth of 165 ft., northwest of the mill. Driving is being carried into virgin ground.

Three prospect churn-drills are at work in section 12, Newton county, Missouri, by the Granby Mining & Smelting Co. At a depth of 200 ft., 30 ft. of ore has been cut in several drill-holes. The clippings indicate a mill recovery of 4 to 5% blende. The prospecting is in virgin territory, although shallow mining has been carried on nearby.

DEADWOOD, SOUTH DAKOTA

REOPENING THE ORO HONDO BY COLORADO PEOPLE.—DEVELOPMENT OF THE HEIDELBERG GROUP.—DAKOTA CONTINENTAL AND MINNESOTA MINES.—SCHOOL OF MINES.

What is regarded as one of the most important and significant mining transactions in this section in several years is the opening of the Oro Hondo by J. T. Milliken, president of the Golden Cycle Mining Co., of Cripple Creek. Mr. Milliken states that he is furnishing all of the funds himself; has no partners or associates in the enterprise other than advisers and engineers. Oro Hondo is a Spanish phrase which may be literally interpreted to mean 'deep ore.' Developments indicate that the name is 'apt and pat.' At a depth of 1000 ft., about 1500 ft. of cross-cutting failed to reveal any profitable orebodies, although the workings are believed to be directly on the strike of the Homestake ore deposits. The shaft is 2640 ft. from the Ellison, the main shaft of the Homestake, and the most southerly on that Company's property. It is stated that the ore-shoots opened on the lower levels of the Ellison are pitching rather steeply to the south and east, and that in order to cut the ore the Oro Hondo shaft must be sunk to deeper levels. Mr. Milliken intends to do this, and has announced that the shaft will be quickly sunk to the 2000-ft. point. The boilers have been fired and two skips of 600 gal. capacity each are in operation removing the water which stood within 50 ft. of the collar. As the mine makes but little water, it is expected that the workings will be drained by the end of this month. Sinking will be undertaken with a full equipment of Ingersoll-Rand jackhammer drills. A boarding house at Pluma, one mile from the shaft, has been rented and equipped for 25 men. E. J. Carr is superintendent.

Fifty business men of Deadwood each pledged themselves, by signing notes, to pay \$100 each to a fund to be used in the development of the Heidelberg group, on Two Bit creek, three miles east of the city. This was a concrete result of work by the mines and mining committee of the Deadwood Business Club, in an attempt to promote the mining interests of this area. The agreement with the owners provided that in return for this \$5000, which was to be expended in exploitation of the ground, the subscribers were to receive a one-half interest in the property. Under the arrangement as perfected, the details of which need not be given here, the first payment of the subscribers was made on August 23, and on that date work was started on the construction of a wagon-road to the camp. Nearly two miles of road was constructed, a part of it heavy work, but which gives a maximum grade of 3% from the mine to the top of the Two Bit divide. This road cost \$750, and the commissioners of Lawrence county appropriated \$250 of the amount. Bunkhouse, blacksmith-shop, assay office, small barn, kitchen, etc., have been built, and within the past couple of months some energetic work has been done underground. The formation is shale of the upper Cambrian, with sills and sheets of rhyolitic porphyry, and through which an 'ore vertical' has been followed for a distance of 160 ft., with the end not in sight and the face still

in ore. The vertical vein, which cleanly cuts the horizontal shales, has a course of north 25° east, and has a width of about one foot. On contact with strata of sand shale this vein is from 3 to 10 ft. wide; this has been removed as the incline adit has been driven. Of the ore taken out, 35 tons, in two shipments, has been sent to the Golden Reward cyanide mill at Deadwood. This assayed \$16 and \$20 per ton in gold, as received at the plant. Several thousand tons of \$3 to \$6 material, which would pay well to cyanide in a mill on the ground, has been piled on the dump. Tub tests of the ore, made at the Golden Reward mill, show an extraction of 91 and 93% on material crushed to 25 mesh and treated without classification or agitation. As the last payment is not due until May 23, considerable in the way of development, it is anticipated, will be done in the meanwhile. The property consists of 185 acres, including several good sites for a gravity mill, with excellent tailing dump and plenty of water. A part of the ground is covered by a heavy growth of yellow pine. A. T. Roos is superintendent and an owner in the property. He located it eight years ago and found the ore three years since.

In the first 17 days of sinking at the Dakota Continental Copper shaft, 17 ft. of depth was made. This is considered good work, as the jackhammer drills which are being used were new to nearly the entire crew. Better headway is anticipated in the future, and it is hoped to have the shaft 1000 ft. deep (it is now 830 ft.) in a comparatively short time.

At a recent general meeting of the Deadwood Business Men's Club, C. C. O'Harra, president of the South Dakota School of Mines, suggested that effort be made to induce the state legislature to make such provision and appropriation as would permit the school to make ore assays for gold for 25 cents. His opinion was that at such a price the school would be enabled to help the prospectors and others of limited means to get reliable assays for a modest sum that would about cover the actual cost of the materials employed. The suggestion was heartily received by the gathering, and it is quite probable that the Club will authorize a strong lobby to go before the next session of the state's lawmakers. Among other matters, Mr. O'Harra touched on the interests of the school, and mentioned that it was rapidly growing both in enrollment and course of study. Many of its graduates hold responsible positions, not only in this state, but are fairly well scattered through the mining districts of the world. It is an educational institution of college rank.

The Minnesota property, at Maitland, was recently examined by E. J. Collins on behalf of Michigan and Minnesota people, and since his return home, and pending his final decision, the workings have been kept pumped. A favorable report will mean the immediate resumption of operations. The Minnesota has been idle for several years, but it is the general belief that the remedy for all its ills lies in sufficient money to equip and develop it in miner-like manner.

BULAWAYO, RHODESIA

BRIGHTER MINING PROSPECTS.—NEW MILLS WORKING AND NEW GOLD YIELDS.—DIVIDENDS IN 1913.—GLOBE & PHOENIX.—GEOLOGICAL INVESTIGATIONS.

A more hopeful feeling now prevails in Rhodesia in regard to the future of the mining industry than has obtained for a considerable time past. It is indeed safe to say that not since the middle of 1910 has there been so much optimism as prevails today, and it might be here remarked that a cheerful outlook is far more justified at the present time than was warranted 3½ years ago. During the boom of 1910, Rhodesian stocks were inflated by operators who made promises that in the majority of cases have never been fulfilled, and moreover are never likely to be. It would have been amazing if the campaign of deceit did not have its own consequences. The

inevitable came in the shape of an aftermath of depression, and during the reaction Rhodesian mining suffered severely. It is to be hoped that the lesson of 1910 will not be forgotten and that in the future there will be fewer regrettable incidents, more clean finance, more businesslike methods, and less 'wild-cats' than in the past. Such things are in large degree inseparable from mining, but in the future Charterland will have to be as free from unpleasant flotation incidents and share-market scandals as is humanly possible. If not, interest in mining in Rhodesia will soon die a natural death. A repetition of some of the incidents arising out of the 1910 boom would effectually close up the pockets of investors, on whom the development of the country largely depends, for many years to come. A period of honest finance and capable conscientious management would quickly bring due reward. For today the mines of Matabeleland and Mashonaland, taken as a whole, are in a more sound condition than ever previously. Ore reserves are much greater, development has proceeded on more businesslike lines, plants are better adapted to the ores which they are intended to crush and treat, and the prospects of an immediate increase in production and profits are undeniably good. Numbers of well informed mining men in both Matabeleland and Mashonaland anticipate that the effect of production by the several new mines which have recently been brought to the revenue earning stage will be to increase the present rate of output by 50%. Today the output is approximately 58,000 oz. fine gold per month.

The Cam & Motor plant has now been working for several weeks and is said to be giving every satisfaction. The Shamva

DORR THICKENERS AND PACHUCA AGITATORS AT THE LONLEY MINE, RHODESIA.

Nissen stamp equipment has had trial runs. Within the next few months the following additions to the monthly gold output may reasonably be expected: Shamva 12,000 oz.; Cam & Motor 7500 oz.; Falcon 3000 oz.; Bell 2000 oz.; and Antelope 1100 ounces. This gives a total of 25,600 oz. and adding this to the 58,000 oz. of present output, it will be realized that a return of between \$3,000 and \$4,000 oz. per month, or say one million ounces per annum, is not an unreasonable anticipation. In any case it looks as if Rhodesia would advance in the list of the world's chief gold producing countries during the current year.

As regards profits it is not at this juncture advisable to attempt any prophetic figures, but it is certain that there will be a substantial increase in earnings. While on this subject, it may be remarked that during 1913 Rhodesian gold mining companies distributed £489,613 in dividends. In addition to this there are the profits earned by the smaller companies, mines operated by small syndicates and tributaries; but it is not possible to give even a rough estimate of the

earnings of concerns of this kind. It is probable, however, that the profits won by small operators if added to the dividends distributed by the large companies would give a total of close to £1,000,000. As to the limited liability companies, the Globe & Phoenix easily heads the list with £280,000 followed by the Eldorado, £90,000, and Lonely £81,301. Six other gold mining concerns distributed earnings among stockholders, the Rezende £17,765; Giant, £13,104; Umniati, £2643; Pickstone, £1800; Susanna, £1750; and Criterion, £1250. One coal mining company, the Wankie Collieries, is in the dividend list with £35,457, and one base metal mine, the Rhodesia Chrome, paid £11,891. This latter industry would expand considerably were railway rates on this material reduced. Reverting again to the gold mines, the overwhelming importance of the Globe & Phoenix to the dividend aspect of the Rhodesian industry calls for remark. This Company accounts for 60% of the total distributed by all the auriferous ventures of Matabeleland and Mashonaland during last year. The third interim dividend of 24 cents per share in respect of last year's operations was paid recently and compares with 42 cents a year previously. But in this regard it should be recalled that at the meeting held on October 27 last, it was announced that the directors had decided, although there had been no diminution in the returns from the mine, to reduce the dividend to provide for capital expenditure of a cash reserve. This decision of the board is limited to the dividend above referred to. The profit earned by the Company during December was £31,000, and ore reserves at the end of the year were estimated at 180,757 tons of an average stoping value of \$27.20. The figures would have been more informative had they been expressed in terms of recoverable value; but at the same time it should be clear that, despite recent criticism regarding the management of the Company, this mine is in a sound condition, and no reasonable minded shareholder should begrudge the lesser dividend if the financial status of the Company is to be further bettered.

Science is considerably indebted to F. E. Studt, who for some years past has been doing excellent geological pioneer work in Northern Rhodesia and the Katanga region of the Belgian Congo. Mr. Studt has from time to time given to the Geological Society of South Africa details of some of his investigations and results, but in his latest contribution, 'The Geology of Katanga and Northern Rhodesia,' he has given a more comprehensive description than previously of a portion of Africa which stratigraphically is but little known, and which, on account of the copper, zinc, and lead deposits which it contains, is of considerable economic importance. Detailed investigation of the geology of these territories has, according to Mr. Studt, shown that there is a striking parallelism with the rocks of South Africa, so that on broad lines, the general South African classification of rocks may be applied there. The general absence of fossils except in a few limited areas, however, limits the scope of determination in regard to age. What Mr. Studt terms the Transvaal system, covers by far the larger portion of this area. The basal beds form a series of carbonaceous puddingstones and shales and are followed by a series of dolomitic rocks with interspersed shales and sandstones, and having copper, iron, and gold deposits. In the years to come much economic results may come of Mr. Studt's investigations. Meanwhile his painstaking work is being noted with interest in Southern Rhodesia, which has played such an important part in the opening of the mineral deposits of the trans-Zambezi territories.

The last annual report of the Bechuanaland Copper Co., which owns 180 claims 120 miles southwest of Bulawayo, covers the term ended May 31, 1913. The mine was closed down in April to enable a reduction plant to be erected. The Siemens-Halske process, tried by Dr. Huth, proved satisfactory for the ore, giving 91% recovery. The ore reserves amount to 30,000 tons of 8% copper ore which is proved by only 10,000 ft. of development work.

BOSTON

NEVADA-DOUGLAS AFFAIRS. — ARIZONA COMMERCIAL SHARES. — CALUMET & ARIZONA. — LAKE SUPERIOR COPPER AFFAIRS. — THE BUTTE, WISDOM & PACIFIC RAILWAY.

Nevada-Douglas shares recently slumped from \$1.25 to 73c., afterward recovering to 85 and 90c. per share. The stock has been weak for several months, but the break through \$1 per share was not generally expected. Reports were circulated that the Company faced reorganization, that it could not finance its leaching plant, and that J. G. Berryhill, the largest stockholder, was 'unloading.' All these rumors were flatly denied by the president, A. J. Orem. The Company's mainstay now appears to be the leaching process with which it is experimenting. The management at Ludwig sends out the interesting announcement that it feels confident the Company has found a way to treat the sulphide as well as the oxide ores without the necessity of giving them preliminary roast, and that in the treatment of the sulphide ores all the iron and sulphur will be obtained as by-products in the form of ferric oxide, red paint, and sulphuric acid. It claims that ferric oxide will have a ready market on the Pacific Coast for at least 2c. per pound, while the sulphuric acid produced will be worth not less than \$10 per ton to the Company itself for the treatment of its oxidized ores. It expects the value of the by-products to be ample to cover the entire treatment cost of the sulphide ore.

If the Arizona Commercial mine had cut the Old Dominion lode, and the Davis-Daly the Belmont vein, the former in cross-cutting on the 1400-ft. level and the latter on the 1050-ft. level, there is no telling what might have happened in a market way on the Exchange and the Curb. Arizona Commercial is an Exchange issue, and Davis-Daly is on the Curb. But both expectations miscarried and the stocks suffered in a market way. A report was current here that Phelps, Dodge & Co. had taken an option at \$5 per share on 5000 shares of Arizona Commercial, and the recent weakness in the stock was stated to have been due to the option not being exercised; but it was also said that the option has until April 15 to expire and action has not yet been taken upon it.

The annual report of the Calumet & Arizona company was well received in Boston from the standpoint of the Company's expansion. Much interest was expressed in the low costs, its new smelter, its acquisitions in Bisbee and the New Cornelia property, and the prospects of increased production. It is thought here that the New Cornelia will prove to be one of the large steam-shovel properties of the Southwest.

The reorganization of the Butte Central Copper Co. is proceeding rapidly, and it is expected that the Company will resume operations at an early date.

At last the Lake Superior strike is officially off, the Western Federation of Miners having stopped all strike benefit payments, it is announced, and closed its supply stores, placing them in the care of sheriffs. As the result of the stopping of the strike, a revival in Lake copper shares is looked for in Boston, and the feeling of investors is much more favorable toward them. Even the assessments are likely to be generally paid in the majority of instances. The United States Smelting, Refining & Mining Co. is expected to eventually consolidate several of the 'drill coppers' in the south range and make a strong company out of them. The latest report of the Michigan state geologist, R. C. Allen, states that there is more unmined than mined copper in the Lake district, and sentiment is much more optimistic that it has been since J. R. Finlay's famous 'revision downward' in the summer of 1911.

Western and English interests are understood to have recently pledged subscriptions running into millions of dollars for the purpose of completing the construction of the Butte,

Wisdom & Pacific railway, which will run from Butte to Jackson, Beaverhead county, Montana, connecting with the Elkhorn mining district in that county, and the French Gulch district in Deer Lodge county. The road will be about 110 miles long and is bonded for \$3,000,000, the property being that of the Boston & Montana Development Co. Freeman I. Davison, of Boston, went early in February to London and interested an English syndicate, headed by Sir Robert William Perks, in the building of this road, and the latter and his engineers will check the route during April, it is understood. The English interests are also supposed to have taken large options on the Boston & Montana stock. A Butte syndicate composed of bankers and capitalists has been formed to furnish additional financing to the mining properties. This syndicate is practically the same as the one which acquired, in the latter part of 1913, 1,094,000 acres of ranch lands in Sonora, west of Juarez, where cattle breeding will be done and the cattle driven to the Big Hole basin of Beaverhead county for feeding, preparatory to shipping them to Seattle and Alaska. This deal was consummated in anticipation of the new railroad being built into the Big Hole country.

NEW YORK

ANNUAL REPORT OF PHELPS, DODGE & CO.—FRAUDULENT MINE PROMOTERS.—FEDERAL LEAD CO. AND AMERICAN SMELTING & REFINING CO. SUIT.

Although the Phelps, Dodge & Co. mines made a record of output in 1913, the income of the Company was \$9,581,495, as compared with \$10,411,535 in 1912. The average net price realized for the copper sold being 15.37c. net cash f.o.b. New York, as compared with 15.51c. in 1912. The dividends were \$7,425,000, \$1,500,000 was charged off for depreciation, and \$173,786 was paid for taxes and other expenses, thus reducing the surplus of \$2,035,185 of last year to \$482,709. In addition to the 151,080,018 lb. of its own copper, the Phelps-Dodge organization sold 50,409,778 lb. of outside copper on commission. In addition the Company produced 5,701,628 lb. of lead, though it is not commonly thought of as a lead producer. Of precious metals, the output was 32,037 oz. gold and 2,073,376 oz. silver. The Stag Cañon Fuel Co. mined 1,322,813 tons of coal. Of the ore mined, about 55% was concentrated and 45% smelted direct. In his presidential report, Dr. Douglas calls attention to the necessity for providing increased ore reserves as the mines are depleted by ordinary mining, and additional property has been acquired by the Detroit Copper Mining Co., and the Burro Mountain and Chamung mines have been purchased. In the Copper Queen and Moctezuma mines, exploration work has disclosed increased ore reserves. It is interesting to notice that the gold and silver output of this Company only amounts to about $\frac{2}{3}$ c. silver and $\frac{3}{4}$ c. gold per pound of copper produced. In the report of the Phelps-Dodge company, Dr. Douglas calls attention to the increased working expenses of that Company through the increased cost of labor, higher taxes, etc. The daily papers in New York have read into this the argument that since working costs are to be higher the price of copper will be higher, an obvious error. As a matter of fact, when the Chile Copper Co. begins turning out copper at 6c. per pound delivered in Europe, and some of the big Western companies work out a successful scheme for recovering the copper in their tailing, it is highly probable that the other companies will have to devise a scheme for lowering their total production cost, even if some items in it do go up.

Judge Julius M. Mayer, of the United States District Court of New York, last week ordered that Albert R. Freeman be granted a new trial. It will be remembered that Freeman was convicted, along with Julian Hawthorne and W. J. Morton, of using the mails for fraudulent purposes in connection with their activities in the promotion of mines in Ontario. Freeman was sentenced to five years in the penitentiary; Haw-

thorne and Morton got one year each, and have served out their term, Hawthorne having utilized his as material for a series of articles which are doubtless more profitable than the mining venture. Freeman has all the while been out on \$150,000 bail. The learned judge now finds that one of the jurors in the trial of Freeman had previously sat on a grand jury which had considered the question of these mining frauds, and that therefore Freeman had not had an impartial trial. Whether the public prosecutor will go to the expense of another trial has not been announced. If a second conviction is secured there is always the doubt as to whether on appeal, it may not be disclosed that the wife of one of the jurymen had a prejudice against men named Freeman, and a third trial ordered. In face of the fact that it has now become almost impossible to secure the conviction of any criminal who has enough funds to take advantage of all the technical evasions possible, while on the other hand no innocent person is safe from charges will bring almost as much abuse as a conviction, and without redress, it is not remarkable that the public is becoming very tired of our present system of judicial procedure.

The disturbed condition in Mexico is reflected in the report of the American Smelting & Refining Co. which shows earnings of 7.47% in 1913 as compared with 10.1% the year before. The gross income was \$13,429,933. By cutting down its depreciation charge to \$1,525,517, or only about half of that allowed last year, the total of charges was kept down to \$3,675,392, leaving net earnings of \$9,756,540. Considering the fact that at times all the Mexican plants of the Company have been shut down, and only the Aguascalientes and the Chihuahua plants have been able to keep up even an approximately steady rate of output, it is cause for congratulation that the shrinkage in earnings has not been greater. The profit and loss surplus amounts to \$18,495,782 and the assets and liabilities show no material change as compared with the two preceding reports.

The suit of the minority shareholders to abrogate the smelting contract between the Federal Lead Co. and the American Smelting & Refining Co. was heard last week. The plaintiffs' attorney pointed out that, in 1903, a sixth contract was made providing that the American Smelting & Refining Co. was to pay for 90% of the lead content of the Federal ore on the basis of New York prices up to 4.10c. per pound, and about that figure to divide the excess. In 1905 Charles Sweeney, then president of the Federal, sold the control of the Company, then vested in himself, J. D. Rockefeller and George J. Gould, to the Guggenheim interests. When the Guggenheim representatives went on the board existing contract was extended for 25 years, providing for a treatment charge of \$8 per ton and the right to deduct freight charges to Denver or Pueblo. Shortly after the International Smelting & Refining Co., at Tooele, became an active bidder for lead ores, and the rates prevailing in the open market became much more favorable to shippers. The contract between the American Smelting & Refining Co. remained in force, and minority shareholders in the Federal, which was barely meeting working expenses for part of the time, naturally were not pleased to be obliged to pay more than the prevailing rate for treatment charges. The counsel for the defense argued that if the contract was profitable in 1905, and it was profitable at that time, it was proper that it should be extended. In 1905 the Federal ores yielded 31 oz. silver and 51% lead, against 15 oz. and 43% in 1913. The decision has not yet been handed down, but the chief point at issue is whether a contract between companies where the contracting parties have neutral affiliations is legal or not.

In the course of the month aluminum lost at least $\frac{1}{2}$ c., the quotations early in the month being 18.50 to 18.75c. for both domestic and foreign prompt delivery, whereas toward the close it was down to 18 to 18.25c. for metal 98 to 99% pure. The demand was not good.

General Mining News

ALASKA

CORDOVA

The disputes regarding mining claims at Chisana were before the court at Cordova on March 12. They include the following: *C. H. Lakaitis v. W. A. Johnson*; *Lakaitis v. James*, claiming No. 7 fraction and \$10,000; *Sutherland v. Jurdy*, No. 3 Big Eldorado; *Woodman v. Eriksen*, No. 1 Chicken; *Cloninger v. Findlansen*, No. 1 Bear; *Nikell and Foster v. W. A. Johnson*, No. 8 Bonanza; *Hussey v. Eriksen*, No. 1 Caribou; *Foster v. Johnson*, No. 1 below Chathenda; *Dattaitis v. James*, No. 1 above Bonanza; *Delander v. McPhail*, No. 2 above Gold Run; *Maddox v. Moskley*, No. 2 above Skookum gulch; *Cloninger v. Moskley*, No. 4 below Big Eldorado; *Costello and Bollinger v. Jurdy*, No. 8 above, fraction, Bonanza; *Delander and Simpson v. James*, discovery annex, Gold Run; *Hertzberg v. Doyle*, No. 3 above Glacier; *Wolfe v. Gates*, No. 1 above Gold Run; and *Tibbs v. Verreau*, No. 1 Skookum gulch. On March 18, Judge F. M. Brown gave his decision in the case of *Lakaitis v. Johnson*, which involved the right of the defendant to title of No. 1 above Bonanza creek, and was in his favor. In the case of *Lakaitis v. James*, the jury could not agree after 56 hours' deliberation, and was dismissed. The amount of litigation is creating much dissatisfaction.

At the Mother Lode mine, an 80-hp. gasoline engine is being installed to drive an air-compressor for 7 Sullivan drills. A cross-cut adit will be driven to give 350 ft. of vertical depth below the Marvelous adit. A winze will then be sunk 300 ft. After this is done a power-plant will be erected, and then a 3400-ft. adit driven to cut the vein at a vertical depth of 1400 ft. The work will take 10 months, at a cost of \$175,000. A road 13 miles long, from Shushanna Junction, the old McCarthy station, to the mine will be constructed, costing \$25,000. Two auto-trucks will then haul 40 tons of ore per day to the railway.

JUNEAU

February returns from the mines on Douglas island were as follows:

| | Alaska Mexican. | Alaska Treadwell. | Alaska United.* |
|-------------------------------|--------------------|----------------------|--------------------|
| Development, feet | 67 | 129 | 1,508 |
| Stock of broken ore, tons.... | 8,665 | —46,776 | —8,072 |
| Stamps working | 120 | 240—300 | 240 |
| Days | 27.4 | 26.8—20.6 | 25.14—27.7 |
| Ore crushed, tons | 17,850 | 61,866 | 33,172 |
| Concentrate saved, tons | 321 | 1,273 | 659 |
| Gold by amalgamation..... | \$19,299 | \$ 95,550 | \$34,056 |
| Gold by cyanidation..... | 20,734 | 82,117 | 24,331 |
| Total realizable value | \$39,632 | \$175,890 | \$57,803 |
| Net profit | 8,518 | 108,594 | 714 |

*Includes the Ready Bullion and 700-Ft. Claim mines.

†Loss.

The work in the 700-Ft. Claim mine consisted principally of stations and ore-bins for the Treadwell, Mexican, and 700-Ft. Claim at the Central shaft.

The following information has been published by B. L. Thane, general manager of the Alaska Gold Mines Co.: The Sheep Creek adit is now within 500 ft. of being connected with the main shaft and this should be made within the next three weeks, as they are continuing not only the work at the adit end, but are also driving from the bottom of the shaft to make the connection sooner. The adit is now in good ore, both at the Sheep Creek end and the end being driven from the shaft, and has been in this ore for over 100 ft. This point is about 2300 ft. below the surface ore

and is a good quality of gabbro, with quartz, galena, and free gold. It is the Ground Hog orebody lying to the foot of the Perseverance slate vein, and is much better here than it is on the main Alexander level. The indications are therefore favorable to a large high-grade body on this level. This is one of the most important developments that has taken place at the property since it has been under the present control, particularly in the indication of the maintenance of good ore at depth.

ARIZONA

COCHISE COUNTY

Metal production of the Calumet & Arizona company's mines in 1913 was as follows: copper, 52,987,383 lb.; silver, 880,915 oz.; and gold, 18,989 oz. The value of precious metals was \$24.36 per ton of refined copper.

A bond issue of \$3,000,000 was authorized by the stockholders of the Mascot Copper Co. at a special meeting held in Chicago on February 28. At the same time the stock of the Company was increased to \$15,000,000. The bonds are to be convertible into stock at \$6 per share after July 1, 1917, and it is hoped that the present stockholders will absorb them on the basis of payment subscriptions one-half in stock at \$4 per share. Recent quotations of the stock at San Francisco have been from \$1.50 to \$2.50. Development at the mine is favorable, but has been slow, and additional equipment is desired.

GILA COUNTY

The Starlight copper and lead mine, 9 miles southwest of San Carlos, is to be cleaned out for examination. As there are between 8000 and 9000 ft. of underground workings, this will take about six weeks. An engineer of the Tri-Bullion Smelting & Development Co. will make the inspection. In 1906 the mine produced ore containing up to 18% copper, 49% lead, and some gold and silver.

PINAL COUNTY

(Special Correspondence.)—Work on the Copperosity group of mines is progressing favorably. J. F. Wagner, the superintendent, has a force of men driving from the 200-ft. level to connect the old workings and has 180 ft. of this work done. Connections will be made shortly. The property is an old one from which considerable ore has been shipped, but it is the intention of the company to devote all present effort toward the thorough opening of the mine. The main shaft is down 270 ft., and the mine is equipped with a gasoline hoist and air-compressor, and machine-drills are used on work in the drift. The company has three silver-gold-lead claims adjoining, on which it will do some development. The district is livening up, and the prospects for the future are bright.

Casa Grande, March 26.

CALIFORNIA

According to the state mineralogist, F. McN. Hamilton, the estimated mineral output in 1913 was as follows:

| | |
|---|---------------|
| Petroleum | \$ 46,000,000 |
| Gold | 20,000,000 |
| Cement | 8,000,000 |
| Copper | 5,500,000 |
| Crushed rock and granite | 6,000,000 |
| Brick | 3,000,000 |
| Borax | 1,250,000 |
| Natural gas | 1,250,000 |
| Silver | 800,000 |
| Quicksilver | 700,000 |
| Other minerals, including asphalt, clay, lead, marble, mineral earths, salt, tungsten, zinc, etc... | 7,500,000 |
| Total | \$100,000,000 |
| The total in 1912 was \$91,472,385. | |

BUTTE COUNTY

The North California Mining Co., in which H. H. Yard was the principal holder, has sold several thousands of acres of land in Butte, Yuba, Plumas, and Lassen counties, comprising all its holdings in these four counties, to the Western Realty Co. of Denver, Colorado. The North California company now passes out of existence.

INYO COUNTY

Most of the lead ore produced in California has come from the Cerro Gordo, Darwin, and Modoc districts of this county, according to Adolph Knopf in *Bulletin* 680-A of the U. S. Geological Survey. The Cerro Gordo has produced about \$7,000,000 in argentiferous lead, and the Darwin between \$2,000,000 and \$3,000,000. The latter district lies at an altitude of 4750 ft., and is arid country, the rainfall at Keeler, 1100 ft. lower, being 3.15 inches. Water is piped 8 miles and sold in 1913 for a 1½c. per gallon for mining and 1c. for domestic purposes. Ore is hauled from the mines to the railway at Keeler at \$6 to \$8 per ton. Freight to the district is \$1 per ton more. Miners' wages are \$3.50 to \$4 per day. There is telephone connection between Darwin and Keeler. The ore deposits are generally inclosed in lime-silicate rocks, although some are in limestone, and small isolated masses of ore are found in the quartz-diorite. The minerals are galena with silver, cerussite, anglesite, and the gangue calcite and fluorite. Several mines are described, and in the early part of 1913 there was considerable activity in the district, especially at the Christmas Gift, Lucky Jim, and Custer mines. The Death Valley railroad, now under construction from Death Valley Junction on the Tonopah & Tidewater line, will be completed and in operation by July 1, 1914. This road, primarily constructed for the purpose of handling the crude borax of the Pacific Coast Borax Co. from its deposits, will make the development of other minerals easier in this region.

NEVADA COUNTY

An adit at the Premier mine is in 1500 ft., and enough ore has been developed to supply a 5-stamp mill for a considerable time. Rich ore was recently opened in a raise. There is said to be good gravel on this property. The Conlan mine will probably be worked again, after seven years of idleness. A 5-stamp mill is to be erected shortly at the Bennefontaine mine at Willow Valley. Richard Martin is superintendent.

PLACER COUNTY

All the mines at Iowa Hill are busy. Twenty stamps are being added to the Pioneer mill. The Mohawk and Copper Bottom are preparing for an active season.

SHASTA COUNTY

Dredging ground near Redding has been sold for \$65,000 to J. K. Kendrick of Willows, Glenn county. Four miles from Redding is the Silver King, shut down on account of a disagreement among shareholders, but it will probably be reopened in a few weeks. It is said that good headway has been made in the East in securing money for the Afterthought Copper company, operating near Ingot. A large tonnage of gold-silver-copper-zinc ore is developed. S. E. Bretherton is manager. Work with the Hall process at the Balaklala plant has been stopped until it has been decided what to do about the recently destroyed crusher plant. S. A. Holman, Jr., is now in charge of the mine.

SIERRA COUNTY

Although there are about 150 men employed at the mines about Alleghany, there is little new to chronicle, and there will be no increased activity until the summer. The same may be said of the Forest City district, where steady work is being done at the Kate Hardy, North Fork, North Fork-Wisconsin drift-gravel mine, and the South Fork. Operations have been resumed at the Miners Home gravel claim at Howland Flat. A mill is being erected at the Mexican mine.

TRINITY COUNTY

The Trinity Dredging Co.'s boat has been laid up most of the winter, awaiting a casting weighing 15,000 lb. This has arrived, after being dropped into the river with a wagon. The dredge will start early in April.

At the Globe mine, near Dedrick, No. 6 level is being rapidly advanced. It will cut the main orebody at a vertical depth of 585 ft. below No. 2 adit. The 20-stamp mill and cyanide plant is treating 120 tons per day, yielding about \$40,000 per month.

TUOLUMNE COUNTY

Diamond-drilling at the old Sledge mine, near Confidence, is to be done by the Tuolumne Deep Channel Mining Co. A thick lava capping covers 130 acres of the property, under which is the gravel deposit.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Three feet of smelting ore has been opened for 30 ft. in the Centennial vein on Leavenworth mountain, and assays return 18.2 oz. gold and 170 oz. silver per ton. D. Kennedy is manager. The Malm mill, partly built here three years ago and left uncompleted, is under option to the Bunker Hill & Sullivan M. & C. Co., of Kellogg, Idaho. That Company has obtained such favorable results from preliminary tests with the process that a working plant is desired. It is undecided whether ore will be shipped to Georgetown for a series of tests or the mill will be taken to Idaho and re-erected, though the former plan, it is believed here, will be adopted. Ore assaying 140 oz. silver per ton has been cut in the east drift on the Rosebud vein on Democrat mountain. G. W. Teagarden is manager.

Georgetown, March 23.

LAKE COUNTY (LEADVILLE)

Work has been started and ground broken for the new zinc smelter at Leadville. The first 50-ton unit is to be ready by August next. It will consist of a crushing plant, eight furnaces, cooling pipes, and a bag-house. The ore to be treated will be low-grade carbonate of zinc, and the products will include oxides used in paint manufacture. Mr. Augustine is in charge of the work.

OURAY COUNTY

A 200-ton blast-furnace is to be installed by the Wanakah Mining Co., while the present 100-ton plant will be held as a reserve. The new furnace will cost from \$10,000 to \$15,000. A sintering machine is also to be installed. John T. Roberts, Jr., is manager. The Ouray-Michigan Mining & Development Co. has been formed to work the Stenographer and Cabinet-maker mines on Oak creek. A 300-ft. cross-cut will be driven, and a raise put up to connect with the old workings.

SAN JUAN COUNTY

At Silverton, machinery is being installed at the Wilfley-Mears plant. A flume is being erected for the treatment of tailing in the lake near the mine and a large tonnage is awaiting treatment.

SUMMIT COUNTY

In the Breckenridge district the Tonopah Placers Co. is overhauling the two Bucyrus dredges for the coming season. For No. 2 boat in the upper part of Swan valley, 51 new buckets have arrived. There are 70 buckets on the line. No. 1 boat, in the Blue River valley, will have 100 buckets. The Reliance dredge is working upstream in French gulch, from its junction with the Blue river. Steam is used to prevent the dredged material from freezing while being washed and on the stacker. The Reiling boat of the French Gulch Dredging Co. will soon be started again. It has a good record.

TITUS COUNTY (CRIPPLE CREEK)

On March 26 there was a meeting of mining men held at Cripple Creek, and a branch of the Colorado Metal Mining

Association was formed, with H. L. Shepherd as chairman and E. P. Arthur, Jr., as secretary. It was decided that the board of directors consist of nine members, three from Cripple Creek, three from Victor, one from Goldfield, one from Independence, and one from Elkton. Local dues are 50c. per year.

IDAHO

According to the report of the state inspector of mines, Robert N. Bell, the various counties of the state produced minerals valued as follows: Ada, \$9034; Adams, \$26,795; Bingham and Bonneville, \$3114; Blaine, \$175,416; Boise, \$604,333; Bonner, \$52,265; Canyon, \$521; Clearwater, \$57,448; Custer, \$892,133; Elmore, \$102,014; Fremont, \$380,143; Idaho,

MAP OF IDAHO.

\$55,311; Lemhi, \$888,926; Lincoln, \$312; Nez Perce, \$3528; Owyhee, \$217,784; Shoshone, \$21,115,812; Twin Falls, \$457; and Washington, \$5209; a total of \$24,572,396.

Owyhee County

Very rich gold ore has been found in the Ruth mine on War Eagle mountain, near Silver City. Great excitement prevails in the district. Portland people own the property.

Shoshone County

The Bunker Hill & Sullivan company pays on April 4 dividend No. 199, amounting to \$81,750. The total to date is \$15,056,000.

MICHIGAN

Houghton County

The report of the Winona Copper Co. for 1913 gives the following data:

| | |
|------------------------------|-----------|
| 'Rock' stamped, tons | 120,806 |
| Refined copper yield, pounds | 1,448,737 |

| | |
|--|-----------|
| Revenue from copper | \$223,299 |
| Total revenue (\$128,506 from assessments) | 419,235 |
| Expenditure | 344,727 |
| Balance of assets over liabilities | 74,508 |

MONTANA

Silverbow County

The recent report of the Tuolumne Copper Mining Co., of Butte, covers work in 1913. The three-compartment shaft was sunk from 2080 to 2400 ft., stations cut at 2200 and 2400 ft., and cross-cuts driven to the vein. On the former level the vein was opened to the eastern boundary, while at 2400 ft. it was only cut on February 20. This level is promising. Ore was mined from the east end of the 1800-ft. level, in two raises at 2000 ft., and at 2200 ft. The output was 2,633,651 lb. copper and 109,705 oz. silver, worth \$200,218. Expenses were \$233,222; dividends \$160,000; cash on hand January 1, 1913, \$202,763; cash on hand at end of 1913, \$12,787.

NEVADA

Esmeralda County

According to the February report of J. W. Hutchinson, assistant general manager of the Goldfield Consolidated, 26,731 tons of ore yielded a net realization of \$182,183. Costs were as follows:

| | Per ton. |
|-------------------------|----------|
| Stoping and development | \$3.32 |
| Shipping expense | 0.17 |
| Dump moving | 0.04 |
| Transportation | 0.10 |
| Milling | 1.95 |
| Marketing | 0.10 |
| General expense | 0.47 |
| Bullion tax | 0.10 |
| Total costs | \$6.25 |
| Miscellaneous earnings | 0.04 |

Net costs \$6.21

Development covered 2688 ft. at \$9.45 per foot, and generally there was nothing of importance from this work. Costs are 36c. per ton higher than the preceding month, due to extraordinary administration charges, and a poor quality of pebbles in the tube-mills; the increased cyanide consumption raised costs 20c. per ton. Two 2½-in. machine-drills are now working on the 500-ft. level of the Silver Pick mine, replacing the hand drilling. Walter S. Norris is superintendent. Rich ore has been opened on three levels in the Florence. The Velvet claim of the Merger company has been sold to the Jumbo Extension company. Since this deal was concluded, the 921-ft. level drift has opened 4 ft. of \$58 to \$70 ore. The Merger company is to continue development on a larger scale than formerly. Up to the middle of last November, a total of \$254,414 has been spent in prospecting, sinking the shaft, and equipment. The 1750-ft. level of the Atlanta is opening satisfactorily.

Eureka County

A shaft has been sunk 900 ft. at the Nevada Central Copper Co.'s property, at Cedar, 50 miles from Buckhorn, but work is temporarily suspended. Deposits of copper ore have been only small on the surface. Nothing was cut in the shaft. H. A. Linke is manager.

Humboldt County

(Special Correspondence.)—James Edmunds has had two men working on a promising copper-gold-silver ore here all winter, and is planning to make shipments to the smelter. The ore assays from \$40 to \$100 per ton. This discovery was made by a couple of Indian boys while hunting deer last fall. Mr. Edmunds has ample funds of his own and

is backing the discoverers, and going right ahead with the property without looking for any outside help financially. John A. Hassell, of New York City, is expected here soon to commence operations on a large scale on his property, which is patented, developed, and ready for a plant. He has about 20,000 tons of 4 to 6% copper ore developed. Curry and DeVoe are extracting ore and getting ready to ship as soon as the roads will permit from their Winnebago mine. They shipped 7 or 8 tons from this property last fall which returned 20.8% copper with several dollars in gold and silver per ton. Frank Baldes has two lessees preparing to commence shipping ore from his property. Former shipments gave about 22% copper with several dollars in gold and silver per ton. W. E. Christiernsson has about ten tons of ore sorted and ready to ship from his best vein on the Champion group, where he has several thousand tons of ore blocked out and ready for a plant on the ground. W. S. Elliott, a well known mining man, is making quiet trips into Sulphur and has several men locating and developing some gold and silver prospects with a view to putting in a 50-ton concentrating and cyanide plant.

On the whole, the outlook is bright for this district, and a boom is neither expected nor desired. A prosperous and steady producing mining camp will be here during the coming season. A custom smelter is needed to handle the ores from the numerous high-grade prospects which are situated along the range for twenty miles or more.

Sulphur, March 8.

A rush has set in to a new goldfield in the Kings' River district, in the northern part of the county, near the Oregon boundary line. The National district is being deserted for the new camp. Reports from the new district are most encouraging and a large number of miners from various parts of the state are going into this district.

The Seven Troughs Coalition mill has yielded \$17,908 from 52 tons of ore so far for March. The winze is below No. 10 level, and shows 110 ft. of ore from where it was cut. In the bottom, 4 ft. averages \$28.35 and 15 in. \$1445 per ton. The gold is worth \$12 to \$13 per ounce.

The property of the Seven Troughs Mining Co. is situated 30 miles northwest of Lovelock, on the Southern Pacific railway. The report covers the year ended December 31, 1913. C. W. Poole is manager.

The Seven Troughs range is about 8 by 24 miles in area, and has a maximum height of 3000 ft. above sea-level. The property consists of 29 claims and fractions. Country rocks are mostly rhyolite, basalt, and andesite. The Fairview-Florence and Lowden veins occur in intrusive basalt dikes. A fault at 600 ft. has completely cut off the veins, and the throw has been so great as not to warrant further prospecting for them. Lessees have secured several blocks of ground, and royalties in 1913 were \$5.79. Cash on hand at the end of 1913 was \$15,547. The present salary list is \$250 per month. The total output of the property to date is about \$275,000.

The annual report of the Rochester Weaver Mining Co. for 1913 gives the following information: The property was leased in 300 by 600-ft. blocks, and ore was opened by three lessees. The Colligan lease produced ore worth from \$22.40 to \$31.74 per ton. The claims have been proved better by lessees than the Company could have in over twice the time. The Company drove an adit 430 ft., and 150 ft. of driving on three veins, showing 5 ft. of ore worth \$8.50 per ton. Development by the Company and lessees was 1164 and 2430 ft., respectively. Ore has been developed to 350 ft. depth, and the leasing system is to be canceled. It is planned to consolidate the Rochester Weaver, Rochester Mines, Nenzel Crown Point, Rochester Belmont, Original Rochester, and Pocahontas properties. Ore shipped from all leases was 953 tons, worth \$30,254, from which the Company drew royalties of \$2783. The year's results left a deficit of \$3582.

NYE COUNTY

Preparations are being made at the Railroad Valley Co.'s property for a resumption of drilling for potash. No. 7 well, which was left at 745 ft., will not be put down deeper, but another one sunk nearby. On April 21 the Tonopah Mining Co. will pay a dividend amounting to \$250,000. At the Jim Butler, a Nordberg hoist with herringbone gear, and driven by a 150-hp. electric motor, is to be installed. The mine continues to develop in a promising way. The West End shipped 48,124 oz. bullion last week, the clean-up for 18 days in March. The Belmont's Western vein being opened on No. 12 and 13 levels is an important orebody. At 1640 ft. the Belmont vein has been cross-cut for 15 ft. in the trachyte formation. During February the 10 producing mines at Tonopah yielded 42,736 tons of ore, worth \$816,455.

STOREY COUNTY

In summing up his reports of the Crown Point Gold & Silver Mining Co., Belcher Silver Mining Co., and Yellow Jacket Gold & Silver Mining Co. for the year ended December 31, 1913, George S. Sturges, the manager of these companies stated: The Jacket mill in 184 days either whole or part operation treated 23,943 tons, of which 6678 tons was from the Crown Point, 2924 from the Belcher, and 14,341 from the Jacket. This ore yielded 3319 oz. gold and 29,049 oz. silver. A considerable part of the year the work of all three companies was concentrated on preparation for and installation of two centrifugal incline sinking pumps in the joint Crown Point-Belcher incline and in necessary equipment for their operation. The Jacket mill was placed in better working condition by the Jacket company and the shaft and incline were repaired jointly by the three companies and are now in better condition than for a considerable time past.

OREGON

Southwestern Oregon has long been known for its widespread and varied mineral resources, among which gold, silver, copper, platinum, and coal are the most important. They have been the subject of investigation for a number of years by J. S. Diller, of the U. S. Geological Survey, and the results have just been published in *Bulletin* 546. The gold rush of '49 landed many a prospector in southwestern Oregon. Placers were opened and placer mining has ever since continued to be a thriving branch of mineral industry. The gold produced in southwestern Oregon before 1881 can not be closely estimated, but it was many millions of dollars, while from 1881 to 1912, inclusive, the production of gold has been \$11,257,772. During the 10 years 1903 to 1912, inclusive, the placer mines produced \$2,014,715 and the lode mines \$1,523,226. Besides the gold and a considerable amount of copper, the production of silver during the same period was valued at \$63,385, platinum \$15,293, and coal \$2,602,122.

JOSEPHINE COUNTY

A 10-day run at the placer claims of Martin and Daniels, 1½ miles below Galice, yielded 184 oz. gold. At the Anderson placer mine, owned by 'Dry Wash' Wilson of Nevada, 8 miles of ditch and pipe-line was completed recently, but a slide carried away 1500 yd. of the ditch. Rich quartz has been found by R. Boswell, at a depth of 15 ft., on Sucker creek, 4 miles from Holland, and near the Anderson placer.

TEXAS

BRAZORIA COUNTY

(Special Correspondence.)—A steady shipment of sulphur from the Freeport mines has been sent by rail to the Eastern and Northern markets since the first of the year, and Texas sulphur is meeting with marked favor with paper manufacturers and chemical buyers who have purchased the Freeport product. The first shipload of sulphur from the Freeport mines is scheduled to leave this port on the steamer

Honduras of the Seaboard & Gulf Steamship Co.'s line early in April.

Freeport, March 18.

UTAH

JUAB COUNTY

The Dragon Consolidated Mining Co. operates at Tintic, and the report covers the year 1913. A large tonnage of iron ore is blocked out ready for the smelters when they desire this class of material. Shipments of quartz are limited at present, as it is low-grade and better suited for milling. Development covered 4765 ft., and was encouraging. The surface adit has been extended along the Governor vein for 1700 ft., opening a large tonnage of mill ore. Results were as follows:

| | |
|--|----------|
| Quartz ore, tons | 3,558 |
| Value per ton in gold, silver, lead, and copper..... | \$19.83 |
| Iron ore, tons | 12,892 |
| Iron, per cent | 55.8 |
| Value per ton | \$3.05 |
| Revenue from ore sales | \$91,988 |
| Operating expense | 92,023 |

SUMMIT COUNTY

Ore shipments from Park City during the past week were 1258 tons. The annual report of the Daly West Mining Co. gives the following information: The mill and hoist were burned on December 28, 1913, but these will be rebuilt by September 1, 1914. The mine produced 1555 tons of shipping and 59,233 tons of milling ore. Of the ore, 13,428 tons came from old workings at 900 and 1550 ft. The larger ore-bodies occur from the 1700 to the 2000-ft. level; but most of the output was from the former depth. The mill treated 59,233 tons of ore in 319 8-hr. shifts, producing 8332 tons of lead and 1598 tons of zinc concentrate. Assays of the crude ore and concentrate were as follows: lead, 5%; silver, 7.7 oz.; zinc, 4.3%; lead, 35.54%; silver, 40.01 oz.; and lead, 4.83%; silver, 18.27 oz.; and zinc, 35.37% respectively. Recoveries were 79.55% of the silver and 99.6% of the lead, according to the mill superintendent, F. W. Sherman. Of the 5038 tons of crude ore marketed, the average was 52.61 oz. silver, 0.0398 oz. gold, 20.06% lead, and 1.86% copper. The year's revenue was \$517,093, a dividend of \$27,000 was paid, and the cash on hand at the end of 1913 was \$23,648.

WASHINGTON

KITTITAS COUNTY

At an altitude of from 2500 to 5000 ft. in the Wenatchee mountains, on the eastern slope of the Cascade range, the Dovre Mining Co. is developing five groups of claims in the Cle Elum and Swank districts. The Northern Pacific railroad is 28 and 16 miles distant respectively from these places. The former district ores contain gold, silver, copper, lead, and antimony, while the Swank ores contain gold and silver. At the Black Bear, Ruby King, Majestic, and Grizzley Bear claims, at Cle Elum, a good deal of encouraging development, 1800 ft. in all, has been done. Assays of ore from these claims, by Falkenburg & Laucks of Seattle, have given high returns. In the Swank claims a total of 500 ft. of work has been done. The Company has been formed with a capital of 2,000,000 shares of \$1 each.

STEVENS COUNTY

On March 25 the lower adit of the United Copper mine cut the vein at 4220 ft. from the portal, and at a depth of 1100 ft. from the surface. The cross-cut went through 27 ft. without reaching the foot-wall. On the east side of the vein is 30 in. of high-grade ore. This adit cost about \$70,000. At a depth of 500 ft. in the Copper King, 700 ft. from the United Copper mine, 4 ft. of gray copper ore has been opened. The new 100-ton smelter may be ready in about 30 days.

CANADA

ALBERTA

The annual report of the International Coal & Coke Co., operating mines and coke-ovens near Colemont, shows that the net profit for 1913 was \$146,829, of which \$120,000 was paid in dividends. Cash on hand at the end of the year was \$40,300. The Company's engineers estimate workable coal at 205,000,000 tons. So far, 3,198,323 tons has been mined.

BRITISH COLUMBIA

During February the Standard mine, near Silverton, shipped 1337 tons of silver-lead ore and some zinc concentrate, giving a net return of \$81,699. No. 7 level is in 2700 ft., and 600 ft. from the point under the shoot from No. 6. The surplus is \$293,332. During 1913 the Hedley Gold Mining Co. treated 70,796 tons of ore yielding \$802,330, with a profit of \$405,255.

ONTARIO

The mineral production of Ontario in 1913, according to Thomas W. Gibson, deputy minister of mines, was as follows: gold, 220,837 oz.; silver, 29,724,931 oz.; copper, 12,941 tons; nickel, 24,838 tons; iron ore, 195,937 tons; pig iron, 648,899 tons; cobalt oxide, 1,188,526 lb.; and nickel oxide, 232,255 lb., with a total value of \$37,794,277.

Sixty feet of ore has been opened on the 120-ft. level of No. 3 Right of Way shaft in the new vein encountered some weeks ago. The vein averages 2 in. wide containing from 2500 to 3000 oz. per ton. The vein is an extension of No. 12, worked on the Princess mine by the La Rose Consolidated company on which a 200-ft. ore-shoot has been opened.

During February the Buffalo mill treated 6163 tons of ore yielding 103,256 oz. of silver. The Hollinger company reports that, during the four weeks ended February 25, No. 8 vein was cut by a cross-cut on the 300-ft. level, and No. 4 vein was cut by a drill at 425 ft. The main shaft is 425 ft. deep. Development covered 635 ft., and 522 ft. of drilling, at a cost of 49.3c. per ton milled. Mining cost \$1.88 per ton. The mill treated 10,042 tons of ore averaging \$17.50 per ton, with 97.4% extraction, at a cost of \$1.31 per ton. Total costs were \$5.52 per ton, and the profits were \$111,679.

COLOMBIA

The Pato dredge produced gold worth \$8300 from 25,500 cu. yd. during the week ended March 3.

MEXICO

MEXICO

During February the Mexico Mines of El Oro mill worked 24 days and treated 11,500 tons of ore. The gold and silver output was worth \$134,670, and profit \$86,690.

DURANGO

(Special Correspondence.)—In 1913 the Desengaño mine, next to the Fortuna, in the Guanacevi district, was worked in a desultory manner, and produced bullion worth \$1,300,000 at a cost of \$200,000. A good deal of ore has been stoped at the Mexico Consolidated, and ore has been opened in the Fortuna. As soon as railway communication is restored, stoping will be started in the latter property. The contact orebody of this district will probably be of considerable size, and produce high-grade ore, as the Desengaño has 100 tons in one pile which will return \$1000 net per ton.

Guanacevi, January 21.

VENEZUELA

(Special Correspondence.)—There is a fair amount of mining activity here, but owners find it difficult to get sufficient labor, on account of the miners being able to recover gold by panning river gravel and stealing it. The class of labor is poor, being chiefly composed of negroes from the West Indies.

Ciudad Bolivar, March 6.

Personal

POPE YEATMAN is expected in New York.

E. H. LESLIE has returned to San Francisco.

P. A. O'BRIEN has left Nicaragua for Colombia.

R. B. STANFORD has been visiting the Canal Zone.

LESLIE H. WEBB was in San Francisco this week.

THOMAS T. READ has gone to Ducktown, Tennessee.

J. H. COLLIER is now associated with the Joshua Hendy Iron Works.

HORACE ROBERTSON has returned to New York from Bisichi, Northern Nigeria.

J. A. VEATCH is investigating the placer deposits of Battle Mountain, Nevada.

W. J. RICKELL has left Seattle for Knik, Alaska, where he will be until October.

H. A. LINKE, manager for the Nevada Central Copper Co., Eureka county, Nevada, is in San Francisco.

FOREST RUTHERFORD and G. D. VAN ARSDALE, of the Phelps-Dodge company, have been visiting the Anaconda smelter.

W. H. STORMS has returned from a mine examination in Tuolumne county, California, and is in Nye county, Nevada, on professional business.

JAMES C. H. FERGUSON, for the past thirteen years Pacific coast sales agent of the Midvale Steel Co. of Philadelphia, has severed his connection with that Company and is now the Pacific coast representative of the William Cramp & Sons Ship & Engine Building Co. of Philadelphia, with his office in the Monadnock building, San Francisco.

WALTER LAIDLAW, who fell dead from heart disease in New York while going home, March 24, was secretary of the International Steam Pump Co., and with his brother Robert one of the founders of the Laidlaw-Dunn-Gordon company of Cincinnati. He was a Scotchman, 65 years of age at the time of his death, and an educated mechanical engineer who was an important factor in the development of the types of machinery manufactured by his firm.

Pig Tin in March

NEW YORK CORRESPONDENCE

February deliveries into consumption exceeded expectations, amounting to 3300 tons. The total visible supply March 1 was 17,308 tons, which was 5004 tons above that of the same date a year previous. Total deliveries for January and February of this year showed a decrease of 300 tons as compared with the same months last year. On March 2 the price was 38c.; on March 9, 37.37½c.; on March 16, 38.05c.; and on March 23, 38.50c. The lowest quotation was 37.37½c., on March 9, and the highest 38.65c., on March 24. Early in the month the market was adversely affected by the erratic behavior of London, and business was also hindered by the storms which cut off communication with interior points. At times in the month there was a steady, though moderate, business, but at no time was there any real heavy trading. Toward the close of the month the supply of the metal was more than ample, the arrivals up to and including March 27 totaling 4718 tons, while there was afloat on that day 3997 tons. Deliveries into domestic consumption in March are estimated at 4500 tons. The auction sale of Banca tin in Holland on March 26 realized an average price of 108½ florins, equivalent to 39.60c. c.i.f. New York or £180 15s., a high figure in view of the fact that it was 56 over the closing price at London (£174 15s.). The amount sold was 2300 tons.

Schools and Societies

COLUMBIA UNIVERSITY has decided to raise the requirements of admission to the school of mines, or engineering, and of chemistry, and generally to elevate and strengthen the course of engineering and technical study, from and after July 1, 1914. The new arrangement will make no substantial change in the age of graduation from the professional school. The last bulletin describes the various departments and illustrates the apparatus used, besides the accommodation obtainable.

The *Harvard Engineering Journal* contains the following articles: 'Notes on the Construction of Section A of the Dorchester Tunnel,' by Philip C. Nash; 'The Catskill Water Supply of the City of New York,' by Charles S. Brisk; 'Scientific Management a Viewpoint,' by Edward L. Lincoln; 'Limnology at Squam Lake,' by Carl Marsh; 'Experiences with the United States Coast and Geodetic Survey,' by P. S. Donnell; 'The Proposed New Water Supply for Oklahoma City,' by Theodore R. Kendall; 'Comparative Application of Gas-Electrics, Storage Batteries, and Trackless Trolleys,' by G. Hall Roosevelt; and several editorial subjects.

New York Metal Market Review

Standing out above all other features in copper are the continued heavy exports. In March there were periods of fair buying on the part of domestic consumers, but the heaviest buying was on foreign account. The producers and agencies have shown a tendency to advance prices on the slightest taking hold by buyers, probably on the principle that domestic consumers usually buy on the rise of the market and that a good movement might be started by such tactics. Domestic consumers, however, have been wary. The demand for brass and copper products is not at all what it should be. Lead descended to the low level of 3.90c. New York, and the exports heretofore referred to have increased. Spelter has not been active to any considerable degree and the course of prices in the month has been downward. Antimony has been dull and some brands are lower. Heavy dealing in tin was wanting and its most noteworthy feature was the large supplies on hand. Aluminum has been quiet and quotations have declined.

COPPER

A remarkable feature in copper is the enormous exports which, up to and including March 27, totaled 40,546 tons. Much conjecture has been indulged in as to where all this metal is going, or, at least, what disposition is being made of it, but after all is said it remains but conjecture. Some say it is going into unofficial warehouses abroad, others declare that the Germans are accumulating enormous stocks which for some time will make them practically independent of outside sources, while others say that foreign manufacturers are loading up at the comparatively low prices which have prevailed abroad. Business reports, especially those from England, would scarcely indicate that unusual quantities are being consumed in that country. The exports in February reached a total of 34,384 tons. The month of March opened dull with electrolytic metal held at 14.50c. cash New York, a price which was followed by a decline for the reason that big consumers refused to pay more than 14.37½c. cash New York. The willingness of at least a few producers to accept the lower price paved the way for still lower quotations, and business was done at 14.25c. cash New York in the first week of the month, domestic consumers taking fair quantities. In the second week foreign buying loomed up strong again. On the strength of the better demand an effort was made to send the price up ¼c., but consumers refrained from touching copper at the higher price, and the 14.25c. level was for the time adhered to. The statement of the Copper Producers' Association for February had little effect on the market. While stocks were shown to have decreased, this was offset by the fact that domestic deliveries in February were about 12,000,000 lb. less than they were in the same month a year ago, while the combined deliveries of January and February of this year were over 29,000,000 lb. less than those of the same two months in 1913. Toward the middle of the month a good business was done with both domestic and foreign buyers, a movement which was precipitated by the dropping; on March 13, of the cash price to about 14.12½c. New York. This quotation held for two or three days, when there was an advance to 14.25c. cash and on April 18 there was a further advance to 14.37½c. cash New York. Buying subsided with the higher price, and between the last advance and March 26 there was little done. Despite the lull, producers on March 24 again advanced their price, this time to 14.50c. cash New York, a figure which, while called the market, could be shaded. The new quotation was based on an advance caused abroad by speculative bull influences and it occasioned much comment to the effect that it was unjustified by conditions existing in the United States. At the time, many of the mills in Connecticut were operating on a 4 or 5-day week basis and the demand for finished copper and brass products could not be called good. The American Brass Co. on March 13 reduced its prices for hot rolled sheet

copper ¼c. per pound, making the base 19¾c. per pound, and on March 16 it reduced various of its brass products ¼c. per pound also, making the base on high brass sheet metal 15½c. per pound and high brass rods 15¼c. per pound. Prime Lake copper was scarce throughout March and prices were nominal, or practically so, at all times. The quotation was 15c. cash in the first few days of the month, with the last previous sale made at 15.12½c. Then 14.75c. cash was quoted, but later the nominal quotation was 15.87½c. cash, where it stood March 25. What selling there was in open market was mostly of arsenical and other inferior brands not suited for high-grade brass work and prices for these ranged down to 14.37½c. cash. On March 25, prime Lake was said to be unobtainable for April delivery. The heavy snow and wind storms which swept over the Atlantic coast states in the early days of March helped the copper wire industry by destroying hundreds of miles of telephone and telegraph wires, mile after mile of poles being snapped off at or near the ground, while in other cases they were stripped of cross-arms. The Waterbury average for February was 15.12½c. per pound.

LEAD

At the beginning of March there were more sellers of lead than buyers. At this time 4c. was the New York price, with St. Louis between 3.85c. and 3.87½c., and it was believed that the bottom had been touched, but before the month was over 3.90c. New York was quoted. The exportations of lead, which had become a subject of comment about this time, continued throughout March, gradually growing heavier until, in the week ended March 21, they amounted to 1800 gross tons. The exports of January and February combined were 1577 gross tons. It is to be remembered, however, that the government statistics do not differentiate between strictly American lead and that smelted in bond, but it is certain that with the trouble in Mexico the bonded lead is far below normal. On March 5, 6, and 7 there was a fair business and the price in the West became stronger at 3.90c. St. Louis, but New York remained unchanged until March 26, when the American Smelting & Refining Co. reduced the price 10c. per 100 lb., or 3.90c. During the greater part of March the market was dull, and toward the third quarter independent interests were willing to make concessions in some instances to get business. When the big interest announced the reduction referred to, the St. Louis price dropped to 3.75c. Needless to say, at these prices the metal is exceedingly cheap, and it is predicted that some sellers will withdraw from the market until conditions are bettered.

SPELTER

Not many features of interest are to be noted in spelter's course in March. When the month began, quotations were around 5.35c. New York, with St. Louis 15 points lower. Then came a decline to 5.30c. New York, a price which held until about March 20, when there was a second decline of about 2½ points, making the New York quotation 5.27½c. and that at St. Louis 5.12½c. Business was dull almost steadily throughout the month, with what demand there was coming from the sheet mills. Toward the end of March it was learned that the European stock of the metal, largely held by a syndicate, were rapidly increasing and the foreign market was soft, but at the same time it was pointed out that the margin between New York and London prices was sufficient to forestall any depressing effect on domestic prices. On March 12 the base price of sheet zinc in carload lots at the mill was reduced 25c. to \$7 per 100 lb. basis.

ANTIMONY

March opened with Cookson's at 7.20 to 7.25c.; Hallet's at 7 to 7.25c. and Chinese and Hungarian grades at 6 to 6.25c. In the last week of the month Cookson's was unchanged, Hallet's was quoted at 6.75 to 7c., and Chinese and Hungarian grades at 5.75 to 6c. The market was uniformly dull and there was evidence that consumers were amply supplied.

The Metal Markets

LOCAL METAL PRICES

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore producer could expect to realize. Ore contracts usually call for settlement on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

San Francisco, April 2.

| | | |
|---|------|---------|
| Antimony | 9 | — 9½c |
| Electrolytic copper | 15½ | — 15½c |
| Pig lead | 4.05 | — 5.00 |
| Quicksilver (flask) | | \$39.00 |
| Tin | 40½ | — 42 c |
| Spelter | 6½ | — 6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 1.—There was a slight drop in copper at the beginning of the week, but it is now firmer with more demand both for domestic and export trade. Total exports in March were 45,973 tons, which beat all records. Lead and spelter are quiet, the former making the first move for several weeks. Tin is easy at 37.50 to 38.87½c. for spot. Antimony is dull, Cookson's being 7.25c. per pound. Bar silver is 58¼c., and 26.81d. per ounce in London, the latter market being steady. Investment stocks in London were buoyant.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

A comparison of the totals of silver exported to the chief European and Asiatic countries during January and February of this year with those relating to the same countries during the first two months in 1913 is full of interest. It will be observed from the figures that last year the Asiatic exceeded the European demand. This year the reverse is the case. Also, the European demand is greater by about £376,000 than that of last year, while the Asiatic demand is less by about £553,000, according to Samuel Montagu & Co. It is worthy of remark that the exports to these five countries alone comprise almost the whole of the exports in the periods mentioned, for those to all other countries combined merely amount to about £141,000 in 1913, and about £184,000 in the current year.

| Exports to: | 1914. | 1913. |
|-------------------|-----------|----------|
| Russia | £ 448,337 | £ 59,840 |
| Germany | 481,450 | 273,500 |
| Netherlands | 154,000 | 375,000 |

| Total | £1,084,387 | £ 708,340 |
|----------------------|------------|------------|
| China | £ 40,000 | £ 115,000 |
| India | 898,265 | 1,376,350 |
| Total | £ 938,265 | £1,491,350 |
| Combined total | £2,022,652 | £2,199,690 |

COPPER

Quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally 1-5 to 1-4c. per lb. more. Prices are in cents per pound.

| June14.71 | | Dec.14.25 | |

Last week the copper market was at first quiet, but by March 24 active buying began and the market stiffened so that on the 25th the price was advanced ¼c. with good sales, especially for foreign shipment, chiefly for May and June deliveries. Reports from the Connecticut valley stated that the brass mills are now running nearly full time, instead of half time, as they have been doing recently. Spring construction work is now beginning, and the telephone and telegraph companies are busy repairing the damage done by the heavy storms last winter. The market at the end of the week was quiet but firm. Exports between March 1 and 26 amounted to 81,092,000 lb., as compared with 76,410,000 lb. in the same period last year.

LEAD

Lead is quoted in cents per pound or dollars per hundred pounds, New York delivery.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb., are given below:

Company Reports

GREAT BOULDER PERSEVERANCE GOLD MINING CO.

The last quarterly statement of this Kalgoorlie company shows the following:

| | |
|----------------------------|-----------|
| Development, feet | 1,536 |
| Broken ore in stopes, tons | 200,178 |
| Value, per ton | \$6 |
| Ore treated, tons | 57,267 |
| Gold yield | \$278,500 |
| Working costs, per ton | \$4.30 |

Generally, development was satisfactory.

MYSORE GOLD MINING CO., LIMITED

This is one of the great gold mines of the world and is situated in the state of Mysore, India. The report for 1913 is replete with every detail, and covers 75 pages with an index and large plan of the mine. The report of Arthur Gifford, the superintendent, shows the following:

| | |
|---|--------------|
| Labor: | |
| Europeans, 171; Eurasians, 108; Indians, 8312.. | 8,591 |
| Machine-drills working | 110.9 |
| Lowest working-level, feet | 3,226 |
| Development, feet | 27,331 |
| Stoping, fathoms | 17,467 |
| Other work, fathoms | 427 |
| Ore reserves, tons | 1,377,102 |
| Rock rejected, tons | 59,616 |
| Ore stamped, tons | 302,662 |
| Sand and slime treated, tons | 264,829 |
| Total gold yield, ounces | 232,178 |
| Revenue | \$4,330,000 |
| Profit | 2,352,000 |
| Dividends | 1,824,000 |
| From 1884 to 1914: | |
| Ore treated, tons | 3,917,109 |
| Gold yield | \$73,344,000 |
| Dividends | 35,530,00 |

APOROMA GOLDFIELDS, LIMITED

This Company owns 1277 acres of gold placer deposits near the Bauri river, province of Sandia, Peru. The report is for

the year ended March 31, 1913. Hydraulic machinery has been installed. The Company's largest reservoir, which was destroyed by a flood in December 1912, has been rebuilt. Two other smaller reservoirs have had their capacity increased. The water-supply available from these sources should in future enable continuous sluicing operations to be carried on upon a limited scale for about eight months in each year. Owing to the accident to the large reservoir, gravel washing during the year under review has been restricted. There was 48,500 cu. yd. of gravel washed, realizing \$7400, showing a net recovery of 15c. per cubic yard.

PREMIER DIAMOND MINING COMPANY, LTD.

This Company operates at Pretoria, Transvaal, and the report for the year ended October 31, 1913, shows the following:

| | |
|--|--------------|
| Ground washed, loads of 1600 lb. each. | 10,434.680 |
| Yield per load, carats | 0.202 |
| Total output, carats | 2,107,983 |
| Value per carat | \$5.32 |
| Value per load | \$1.08 |
| Cost per load | \$0.62 |
| Total value of output in 1913 | \$11,216,000 |
| Total value of output in 1912 | 9,620,000 |
| Stock of diamonds unsold at October 31, 1913 | 2,210,000 |
| Operating profit | 4,061,000 |
| Dividends for Company | 1,920,000 |
| Royalty for Transvaal Government | 2,400,000 |
| Carried forward | 528,000 |

MONTANA-TONOPAH MINES COMPANY

Monthly outputs and details of mine development of this Company have been given regularly in this journal, and results for the year ended August 31, 1913, need only be summarized now. Arthur H. Lawry, the superintendent, reports as follows: Development covered 10,243 ft., against 10,076 ft. in 1912. This work was confined to the opening of the different veins, and to the exploration of their walls and blocks of unexplored territory on the various levels. Although no new veins were discovered, bodies of good mill ore were found in the undeveloped portions of each of the known veins. The most important discoveries made during the year were in the Shaft and Triangle veins, in which good bodies of high-grade ore were found. The cost was \$4.86 per foot, a reduction of 37c. from 1912. Ore reserves are roughly estimated at 32,000 tons, as the veins are broken and faulted. Mining cost \$2.62 per ton. The mill treated 52,402 tons, yielding 8978 oz. gold and 784,494 oz. silver, worth \$665,208. The recovery was 91.2%. Silver averaged 61.15c. per ounce. A dividend of \$100,000 was paid, \$156,757 advanced to the Commonwealth Mining & Milling Co., and cash assets are \$312,051. Detailed costs of mining and treatment will be given in another issue of this journal.

COMMONWEALTH MINING & MILLING COMPANY

This Company is a subsidiary of the Montana-Tonopah Mines Co., and operates at Pearce, Arizona. A new 300-ton mill is now in operation. The report covers the year ended April 30, 1913. The superintendent, Edgar A. Collins, says in part: The past year has been one of preparation entirely, no ore having been shipped. A certain amount of ore was necessarily broken in the development and stope preparation work. This has been hoisted to surface and placed on the mill ore dump, or has been stored underground at some suitable point. Shipments of old tailing, averaging 50 tons per day, have been made by the Calumet & Arizona smelter under its contract with this Company. Development covered 6773 ft., of which 82% was away from the vein, at a cost of \$4.11 per foot. Station and ore-bin cutting cost 12.2c. per cubic foot. The total ore reserves, averaging \$5.35 per ton, are worth \$1,378,000. This is down to about No. 7 level. Churn-drilling was done in 1912, but the ground was so hard and fissured

that it was abandoned. The cost was \$9.57 per foot. The new mill cost \$335,271, supplied by the Allis-Chalmers Co., Mine & Smelter Supply Co., Oliver Continuous Filter Co., Stearns-Roger Manufacturing Co., Merrill Metallurgical Co., Pacific Tank & Pipe Co., and the Ingersoll-Rand Co. B. A. Bosqui is mill superintendent.

VAN RYN GOLD MINES ESTATE, LIMITED

This Company operates on the Rand, and the report is for the year ended June 30, 1913. It may be summarized as follows:

| | |
|---|-----------|
| Ore reserves, tons | 2,064,529 |
| Value, per ton | \$6.50 |
| Ore treated, tons | 456,190 |
| Gold recovered | £637,788 |
| Dividends | 237,500 |
| Transvaal Government tax | 25,598 |
| Miners' phthisis expenses | 4,618 |
| Costs per ton: | |
| Mining | \$1.85 |
| Development | 0.45 |
| Milling | 0.46 |
| Sorting, crushing, and transport | 0.16 |
| Cyaniding sand and slime | 0.36 |
| General, London, and Johannesburg | 0.54 |
| Total | \$3.82 |

DALY-JUDGE MINING COMPANY

The Daly-Judge Mining Co. operates an area approximately 4000 ft. wide and 11,000 ft. long, on the trend of the Ontario-Daly-Daly West vein system at Park City. Another group of claims, of 120 acres, is in the Big Cottonwood cañon, two miles west of the main property. Formations are of altered sedimentaries, quartzite, limestone, shales, and quartz-dolerite. Dikes of diorite and porphyry are found filling several fissures, according to a geological report by George D. Blood. Normal faulting is a feature of the Daly-Judge area. Ore deposition is closely associated with fissuring, the ore occurring as fissure filling, as replacements of wall rocks and of certain beds some distance from the fissures. Ore of milling grade greatly exceeds in quantity that which may be marketed directly, but milling is done to separate zinc from lead-silver minerals. The mine is operated through an adit 6600 ft. long, and a vertical shaft 1600 ft. deep. The former cuts the latter at its 1200-ft. station, and serves as an outlet for ore to the shipping bins and mill in Empire cañon, near Park City. Waste is hoisted to the collar of the shaft. Levels have been driven from the shaft at 500, 700, 900, 1100, 1200, 1400, 1500, and 1600 ft. below the collar. Three levels have been extended from the Daly West into the Daly-Judge, corresponding to the latter's 1900, 2100, and 2300-ft. levels. When completed, the Snake Creek tunnel will serve as an outlet and drainage channel for the southwest portion of the property. The general superintendent, O. N. Friendly, reports to the general manager, G. W. Lambourne, as follows: A large number of improvements were made to the main adit, such as 8000 ft. of new rails, replanking, timbering, etc. Excluding work done in ore, development covered 16,461 ft. Good ore was mined from the Daly vein above the 500-ft. level. At 700 ft., 5912 tons was extracted; 17,533 from 900 ft. and 5881 from 1100 ft. Fissure No. 1222, the Middle and Back veins are opening well. On the 2300-ft. level, on the Daly and Ontario veins, work covered 1654 ft. Top-slicing was adopted during the year for the Daly ore-bodies. The mill treated 48,943 tons of ore in 376 days of 8 hours each, producing 11,909 tons of lead concentrate, and 3719 tons of zinc middling. Ore sold amounted to 4954 tons. The year's revenue was \$617,393; balance from 1912, \$524,478; expenses, \$469,521; dividend, \$180,000; balance at end of 1913, \$492,350.

Decisions Relating to Mining

EAST TINTIC DECISION REVERSED

In a decision rendered February 2, 1914, the Secretary of the Interior has reversed the former ruling of the Interior Department in the matter of the East Tintic lodes. (41 Land Decisions 255). The effect of the new ruling is to give the Department's approval to discoveries of mineral made through diamond drill borings and to permit such borings to count as common improvements toward patent. The new decision has caused rejoicing among Utah mining men.

CANCELLATION OF MINERAL ENTRY—EFFECT OF

Where a mineral entry has been finally canceled by order of the Commissioner of the General Land Office after application for patent and after acceptance of purchase money, the mere fact that the money remains on deposit in Washington does not create any equity in the land in favor of the applicant. He is relegated to his former position as a mere locator and if he fails to perform his annual assessment work during the ensuing year, his claim becomes forfeited upon the subsequent location by another person, made after the expiration of said year in which work was not performed.

Shank v. Holmes (Arizona) 137 Pacific, 871. January 14, 1914.

CONFLICT BETWEEN CALLS OF NOTICE AND BOUNDARIES

In a suit on an adverse claim the defendant proved that his location end-stakes were placed at a greater distance from the discovery point than called for in the location notice. Defendant claimed that the position of the stakes in the ground should prevail over the calls of the notice. When the survey for patent was made the lines were swung within the limits of the marked boundaries so as to include some rich ground claimed by plaintiff under a location junior to defendants. Held that defendant could not make an excessive location and then remodel it to suit subsequent developments, and that in a case such as the one at bar the calls of the location notice should fix the limits beyond which stakes could not be set. Title to the disputed area was awarded plaintiff as being subject to the valid junior location.

Swanson v. Koeninger (Idaho), 137 Pacific, 891. December 24, 1913.

ROUND MOUNTAIN CASE AGAIN

The Supreme Court of Nevada has reversed itself on rehearing in the case of Round Mountain Mining Co. v. Round Mountain Sphinx Mining Co., granting a new trial. The former ruling of the court that where the patent upon its face showed a conflict in area and ambiguity, the field notes were admissible in evidence to explain the ambiguity and determine priority of location was reaffirmed. The court, however, reconsidered its former ruling that priority of a location as shown by the field notes would open the case to a determination of its validity by the courts, as other elements such as discovery might enter into the matter. It was held, moreover, that as respondent had failed to adverse during application for patent it was forever estopped from raising questions not directly appearing from an inspection of the patent and field notes, that the findings of the Land Department cannot be set aside by a mere showing of apparent conflicts in priorities in the field notes, and that no conclusion of law in favor of the senior locator can be presumed therefrom.

Round Mountain Mining Co. v. Round Mountain Sphinx Mining Co. (Nevada), 138 Pacific, 71. January 3, 1914.

Book Reviews

PHYSICAL MEASUREMENTS. By A. Wilmer Duff and Arthur W. Ewell. P. 244. Ill., index. Philadelphia, 1913. For sale by the *Mining and Scientific Press*. Price \$1.50.

The third edition of a text-book on physical measurements designed for college students and written by two professors of the Worcester Polytechnic Institute. The book is intended for laboratory work where the apparatus mentioned is at hand.

ANNOTATED BIBLIOGRAPHY OF IOWA GEOLOGY AND MINING. By Charles Keyes. Iowa Geological Survey. Vol XXII. Pp. 908. Des Moines, 1913.

This is an unusually complete bibliography and is of interest and value to all who have occasion to study either geology or mining in the Middle West, since Iowa is but a portion of that great region, and papers descriptive of it are in the main equally descriptive of much of the surrounding area.

THE ELECTRIC FURNACE. By Alfred Stansfield. P. 415. Ill., index. McGraw-Hill Book Co., New York, 1914. For sale by the *Mining and Scientific Press*. Price \$4.

On account of the rapid development of the electric furnace since the first edition of this book, in 1907, the present edition was necessary in order to bring the work approximately up to date and to include all recent developments of importance. The second edition has been in preparation for three years, and contains double the quantity of material that appeared in the original book. The history of electric smelting, design and operation of furnaces, and results of laboratory furnaces are subjects which are interestingly covered at some length. The chapters on the manufacture of iron, steel, zinc, copper, nickel, and other metals by means of electric furnaces are especially pertinent and of great value. Mr. Stansfield has contributed an excellent work on a subject which is of growing interest to all modern metallurgists.

THE MINING MANUAL AND MINING YEAR BOOK FOR 1914. By Walter R. Skinner. P. 1240. Ill., index. Walter R. Skinner, and *Financial Times*, London, E. C., 1914. For sale by the *Mining and Scientific Press*. Price \$6.

This indispensable compilation is now in its twenty-eighth year, and appears with its usual promptitude. The author's preface briefly covers mining throughout the world during the past year, and the current year's prospects. Seventeen pages give statistics of gold outputs of the leading mines. As was stated in the last issue, the volume is divided into two main divisions, 'African' and 'Miscellaneous,' occupying 390 and 540 pages respectively. These give all necessary information on mines in Africa and the rest of the world, whether they produce gold, silver, copper, lead, or zinc. A directory of mining directors covers 202 pages; mining secretaries, 43 pages; mining and consulting engineers, mine managers, etc., 35 pages; mining terms, 8 pages; and an appendix with new company registrations up to the end of January 1914, 7 pages. This book will be found useful in libraries, editorial rooms, mining companies' offices, stockbrokers' offices, and by mining men in all branches of the industry.

DETAILS OF CYANIDE PRACTICE. By Herbert A. Megraw. P. 215. Ill., index. McGraw-Hill Book Co., Inc., New York, 1914. For sale by the *Mining and Scientific Press*. Price \$2.

Although the millman who operates a treatment plant is the best person to explain the sundry troubles and general results met with, yet the man who has been through it all,

and visits other mills, is well able to study their practice and criticize or compare it with his and other experiences. The descriptions of plants in this volume were first published in 1912 and 1913 in *The Engineering and Mining Journal*, and attracted a good deal of attention, followed by some discussion on the points raised. The author's examinations included the following: the Cobalt district, Ontario; Nipissing high-grade mill; the Hollinger mill, Porcupine; cyaniding at the Dome mill; practice in the Black Hills, South Dakota; the Liberty Bell mill, Telluride, Colorado; practice at Cripple Creek; practice at Tonopah; practice at the Nevada Wonder mill; methods at Republic, Washington; the mills of Grass Valley, California; the Gold Road mill, Arizona; two Arizona mills; and discussion on various subjects. The presswork is generally good, but several half-tones are very poor.

HOW TO BUILD UP FURNACE EFFICIENCY. By James W. Hayes. P. 126. Ill. Published by the author, Chicago, 1914. For sale by the *Mining and Scientific Press*. Price, \$1.

The way to build up furnace efficiency, according to Mr. Hayes, is to teach the fireman how to do it, not by relying on a consulting engineer's infrequent visits. The logic of this argument compels respect, and Mr. Hayes has contributed much toward putting his idea into practice by writing this little book in so readable a form that the aforesaid fireman can be reasonably expected to read and digest it. But the reviewer closes the interesting little volume with words suggesting that much of what has been directed at the fireman is really intended to produce an effect on the manager, a suspicion confirmed by the epigram on page 26: "It is a short distance, as the crow flies, from the manager's office to the boiler room, but it is a dickens of a long road by the route the manager travels." Not a few managers make a fad of motion study in the shop, while dollars are being shoveled away in the boiler room. The book is so interestingly written that it holds the attention of the general reader, and even the man who only uses coal for household purposes ought to be able, as a result of the useful hints received, to save many times the cost of the volume.

THE COPPER HANDBOOK. By Walter Harvey Weed. Vol. XI, 1912-1913. P. 1413. Published by the author, Houghton, Michigan, 1914. For sale by the *Mining and Scientific Press*. Price \$5.

The long expected and much needed revision of the Copper Handbook has been accomplished and in the new volume is found an enormous mass of useful information. Mr. Weed, the new editor, follows the lines laid down by the founder, the late Horace Stevens, but has introduced features that give additional value to the work. The material is classified into five parts. The first includes the usual detailed descriptions of mines in North America. The second is a geographical index which permits the quick finding of a mine when the name of the company has slipped from mind. The third comprises descriptions of mines in foreign countries and here the detail covering South American countries seems sure to be of large immediate value. The fourth part is a handy compendium of the significant statistics of copper and copper mining. The fifth part is a register of the dead copper mines with reference to the earlier volumes in which details will be found. Mr. Weed has wisely continued the policy of including all mines that produce copper even if the latter is incidental. The book becomes therefore, at least in part, a general register of metal mines. While from this point of view it is not complete, as could hardly be expected, it is the best book available in this field. The careful reader will note that the new editor's criticisms, if couched in less picturesque language than occurs in the earlier volumes, is not less penetrating and frank and it is evident that 'The Copper Handbook,' which has become an institution, has fallen into good hands.

Industrial Progress

The Neverleak Coupling

Air leakage is one of the prolific sources of loss around a mine. At 80-lb. pressure it is calculated that a $1/64$ -in. hole permits a loss of 0.33 cu. ft. per minute, and a $1/32$, of 1.33 cu. ft. An air wastage of 100 cu. ft. per minute, the equivalent of the output of a small compressor, would result from 75 leakages of that size. At the higher pressures now coming into use the leakage would be much greater. In many a

mine the pipes sing constantly and it is, unfortunately, the exception to go into a stope or a heading and not find one or more couplings that leak. The old style malleable iron union depends upon a flat gasket. It must be screwed up tight and the gasket must be in place or there will be leakage. In the hurry of getting work started these simple precautions are often neglected, and if no gasket be nearer than the shaft bottom, the coupling may even be put in service without any. Many attempts have been made to make a simple coupling that would avoid these difficulties, and the Cleveland Rock Drill Co. is now placing on the market a 'Neverleak' hose coupling which, it is believed, does so. The principle in-

Skroud, adding to length of bearing and preventing dirt from entering coupling.

Heavy locking lugs—absolutely no breakage.

U Shaped Gasket which never leaks. Gasket being in groove cannot be lost.

Groove for "Never Slip" Clamps.

Large, unobstructed air passage.

Coarse rounded threads on hose ends insure clamps holding hose tight on coupling.

Long bearing points, insuring long life.

Coupling has only three parts—male and female ends and Gasket.

DETAILS OF THE COUPLING AND CONNECTIONS.

involved is clear from the attached figure. In place of the plain gasket of the ordinary union, a V-shaped rubber gasket is placed in a groove in such manner that the air which would ordinarily cause the leak, expands the fold, pressing one side against the male and the other the female end of the coupling. Being held in a groove it is secure from loss. The coupling may be put together without a wrench, has no projecting parts to catch as the hose is dragged, and is so made, in 12 sizes, that any male end can be joined to any female end, whether hose or pipe. Construction details are shown in the figure.

RUMSEY & Co., LTD., are distributing a small folder giving details of their power pumps for industrial purposes, including belted and electric-driven triplex types.

Tandem Electric Locomotive

We print herewith a picture of the 4-ton tandem locomotive used by the National Copper Mining Co. at Mullan, Idaho, and described in the *Mining and Scientific Press*, February 21, 1914. The weight of each unit is 8000 lb.; length, 10 ft.

TANDEM LOCOMOTIVE.

5 in.; height, 3 ft. 2 in.; width, 4 ft.; journals, $2\frac{3}{4}$ by 4 in.; diameter of drivers, 24 in.; wheel-base, 3 ft. 2 in.; gage, 2 ft. There are two 901 B Westinghouse motors, running at 250 volts. The locomotive was built by the Baldwin Locomotive Works, and the object of having two units was to get adequate power on a narrow track, distribute the weight on the rails, and furnish the extra power needed on the line outside the mine without increasing the train crew.

The DENVER FIRE CLAY Co. now has ready for distribution its 1914 catalogue, containing complete descriptions and pictures of all the various furnaces and fire-clay goods made by this pioneer firm. In comparing this with older editions, one is at once struck with the progress made in the use of gas and oil as fuel in metallurgical work. Indeed, the Company advises that "if you are using coal, coke, or wood, you are behind the times and are losing money on your fuel bills." It was but a few years ago that it was unsafe to use an oil furnace because the irregular distribution of the heat made it impossible to secure uniform results. That day, however, seems definitely to have passed, and a bewildering variety of tried furnaces is now offered for sale. Attention is called to the fact that goods sold by the Denver Fire Clay Co. are manufactured entirely by that concern, which not only mines, shapes, and burns the clay, but casts the iron parts as well, and, in short, controls the whole process of manufacture. As no mine is complete without some laboratory, this catalogue will be in wide demand.

RECENT studies of mine-rescue apparatus point to a reaction against the use of the helmet type of pneumatophors. The trouble is that it seems impossible to always make a close and safe connection between the helmet and the wearer's face because of the irregularity in outline involved. In cases where poisonous gases are entered, which are not odorous, there is a constant and unsuspected danger. For this reason the mouth-breathing apparatus is preferred, and in a recent report by Haldane the helmets are severely criticized.

The STEVENS-ADAMSON MFG. Co.'s catalogue, section 3, No. 19, contains useful charts for calculating capacities and horsepower of belt-conveyors, complete descriptions of 'S-A' apparatus, and an impressive set of pictures illustrating the wide variety of uses to which the belt-conveyors built by this Company are put.

EDITORIAL

COOL, in Eldorado county, California, comes forward with a story of a water can left standing on an ore pile during an electric storm, and which was found, when the clouds cleared, to have become gold plated. Our correspondent vouches for the facts, so we can but pass the matter on to the Electrochemical Society for discussion at New York. We had always understood that clouds were silver lined, but apparently they do things differently in the Golden State.

LITIGATION over rights in disputed ground seems likely to lead to a bitter controversy at Tonopah, Nevada. The question at issue is between the Jim Butler and the West End, and repeated conferences have been held in hopes that a compromise might be effected. Apparently all such expectations have been given up and the courts must decide the matter. It is greatly to be regretted that the long record for harmony maintained at Tonopah is to be broken.

'GOLD is where you find it,' according to the miner's adage, and from Siberia to the Rand the trail of the prospector is marked with mineral locations attesting the truth of this statement. Mr. Douglas Mawson, of Adelaide, Australia, who has recently returned from a two-year exploration of Antarctic regions, reports the discovery of many mineral deposits in this far-off land. While their extent could not be determined owing to the depth of snow and ice, many of them are reported as rich, and a coal bed of large extent was also uncovered. It may be that further exploration will prove that the rainbow does end in the Antaretics.

A FIRST regular meeting for the purpose of organization of the Nevada Safety Commission will be held at Reno on April 18. It will be remembered that a Safety First Congress was held at Reno under the auspices of the University of Nevada last January. At this time a committee of nine was appointed by the Governor to consider the advisability of a permanent organization. The meeting on April 18 will be for the purpose of permanent organization and the adoption of the constitution and by-laws. The work of the organization will be directed by a board of 75 directors, which will be subdivided into six committees for the administration of the different branches of the work. The committees will be known as the mining, transportation, agricultural, power, varied industries, and

publicity committees. The subject of proper representation at the Panama-Pacific Exposition will also be discussed at this meeting. From both a humanitarian and efficiency standpoint, the safety-first movement is of prime importance to both employer and employee, and as such it is to be hoped that the work of this new organization will meet with that measure of success which such an organization warrants.

MATTERS of much interest to mining men and metallurgists not directly concerned will be presented at the meeting of the American Electrochemical Society in New York next week. At the Saturday morning session, Mr. E. A. Smith is to give a general lecture on progress in leaching and electrolytic treatment of copper ores in South America. One does not need to be concerned with the technology of electrochemistry to appreciate the importance of the Chuquicamata to the copper market, and Mr. Smith's work in connection with the treatment of Chuquicamata ore is sure to be wide reaching in result. His paper will be followed with a number of others dealing with questions of ore treatment and the advance announcement indicates that the New York meeting of this most excellent society will be quite up to the standard already set.

MINERAL production of Mexico for November 1913, as compiled by the Bureau of Statistics of the Department of Hacienda, shows a material decline in practically all branches of the industry during this period as compared with the same period of the preceding year. Coin silver, minor mineral products, and petroleum showed a slight increase in exports, but these by no means compensated the general decline. The exportation of gold for the month under review amounted to \$2,561,941, while that of the previous year was \$3,561,599, which is a loss of \$999,658. The decline in silver production was even more pronounced, the exports for November 1912 being \$8,158,786, while in 1913 they fell to \$4,432,277, being a decline of \$3,726,509, or about 48 per cent. The decline in copper exports was most significant and due of course to the rebel activity in northern Sonora and Chihuahua. The exports of copper reported for November 1912 totaled \$2,177,654, while in 1913 they fell to \$243,216, a decline of \$2,177,655. The decline in the exports of other minerals during November 1913, as compared with the same month of 1912 was as follows: antimony, \$52,644; asphalt, \$41,526; marble, \$62,500, the total production for November 1913 amounting to only \$2000; graphite, \$42,200, there being no production during November 1913; the decline in lead was \$382,000; and zinc, \$72,323, there being no zinc exported during November 1913. Petroleum showed a gain of \$599,637. The total valuation of the mineral exported during November 1913, according to the government's statistics, was \$9,121,065, as compared with \$16,066,692 for the same period of the preceding year.

GROWTH of the Canadian Mining Institute has necessitated the establishment of a monthly bulletin in order that members may be kept in touch with the activities of the organization. So long as the Institute was small, personal letters and attendance at the annual meetings served this purpose sufficiently; but the Institute is no longer small, its membership is widely scattered, and, as is true of other national engineering societies, only the minority can be expected to attend the meetings in person. Those who have enjoyed the hospitality of the Canadian Institute, while rejoicing in the recognition of success implied by the larger membership, will hardly escape a feeling of regret that the old days of a small circle of friends and men who are more to each other than names has passed. Prosperity has drawbacks as well as advantages.

The Marañon Placers Again

The recently issued first annual report of the Peru Gold Placers, Incorporated, contains a reproduction of the report upon the Marañon placers by Mr. Raymond McCune with various accompanying papers. It gives practically no information not made available months ago, but is prefaced by a letter from the president of the corporation, Mr. David T. Marvel, which contains the statement that "Your directors feel convinced that no question can be raised as to the conservatism, honesty, and substantial accuracy of Mr. McCune's report." This raises a question as to what constitutes "conservatism" and "substantial accuracy" in the minds of Messrs. William R. Bassett, Henry H. Bowman, Alexis I. du Pont, Otto R. Hartmann, David T. Marvel, Charles S. Miller, and John J. Raskob, who are the directors in question. As we pointed out editorially, February 7, the report is the very antithesis of conservative, if judged by the standards of any intelligent engineer familiar with the testing of placer ground, and it is a play on words to apply to it even the elastic term "substantial accuracy." Another interesting feature of the report is the statement that "Mr. Robert S. Miller, of Miller, Franklin & Company, Efficiency Engineers of New York City, went to Peru to check Messrs. McCune, Henry, and Menard, and his report fully confirms their findings." Mr. Miller's own letter, which is published with the report, is obviously that of one totally inexperienced in placer examinations, one who is merely an onlooker. Boiled down to facts, he states that he saw gold in pannings from over 75 per cent of the test holes. So did, it will be remembered, certain investigators in Santa Domingo of whom we had recent occasion to write. This is not "checking" an examination, and Mr. Miller's "belief" that the value of the property will be greater than Mr. McCune has estimated, is deserving of all the weight attached to the belief of any other amateur and no more. Wonderful things are expected of 'efficiency engineers' in these modern times, but some limits must be respected.

The whole matter as heretofore presented to the public is one of belief, not of proof. Furthermore, the basis for the belief as yet advanced is not convincing to men experienced in such matters. Indeed, capable engineers who have made examinations, and thorough ones, in the very district concerned, laugh at the claims made by the Peru Gold Placers company. We are disposed to believe that the directors are allowing their hopes to cloud their judgment, but others are not so charitable and protest that the whole matter is a thinly disguised scheme to milk the public. Certainly any director who cares for his reputation and who does not know better than to allow his name to be used as in this report, would do well to seek advice from some experienced as well as trusted friend.

The Radium Bill

Washington has been much concerned these past few weeks with various proposals to amend the mining law. We have, from time to time, commented on the different bills, and in our 'Special Correspondence' columns this week we present a general summary of the present situation. It now seems certain that the commission to codify the mining laws will be created, that the Alaska coal lands will be leased, and that acts providing the leasing of unreserved coal, oil, phosphate, and potash lands, and the 'radium' bill will be passed in some form. Probably none of these has excited as much feeling as the radium bill. As reported to the Senate in amended form this reserves to the United States a prior right to purchase at market price, radium-bearing ores produced from claims on public lands hereafter located. It also provides funds for erecting and operating a laboratory for treatment of radium ores for the government hospitals. These proposals have called out violent opposition, especially in Colorado, and the proponents have been equally positive that a vital matter was under consideration. We confess that we have been unable to see any adequate reason for all this excitement.

The therapeutic properties of radium are still largely undetermined. In treatment of certain diseases, notably cancer, beneficial results have been obtained, and competent medical practitioners believe that with large quantities to work with, even better results, amounting possibly to cures, could be secured. This, however, is far from being as certain as many have been led to believe by the highly sensational reports that have been printed. If, however, any such benefits are possible it is certainly proper that every effort should be made to realize them. In the meantime private concerns are producing radium, though in small quantities, and the price is both high and speculative. It is altogether probable that the material can be furnished to the government hospitals at lower rates under the terms of the bill through purchase of the ore as proposed than through buying the finished material as now. The existing refineries control their own supplies of ore.

They will be in no way dependent upon the Government in event of passage of the bill. The only harm that can come to them is through the breaking of a potential monopoly, since the Secretary of Interior will have authority to sell any radium or by-products not needed for government use. Lands located prior to the passage of this act will not come under its provision, and, since the matter has been debated for some months, during which time the search for such lands has been active, it may be safely assumed that the known lands are already located. The ore taken by the Government is to be paid for at market rates ascertained (not fixed) by the Secretary of Interior and announced on the first of January and of July for each year. Upon tender of ore by the miner and its refusal by the Department, all the rights of the latter cease. In effect the Government reserves a perpetual option to purchase the ore at the market price. It is hard to see how this can work out to much if any hardship. It is true that it is a departure from precedent, though that alone is not sufficient ground for condemning it. The real value of radium is still largely undetermined and the money appropriated in this bill is properly to be considered as devoted to experimental research. It may turn out well or it may prove to be wasted, but the amount is small in proportion to the possible benefits.

Powdered Coal in Metallurgy

Pulverized coal is to be used as fuel in the reverberatories at Anaconda if all goes well. One of the furnaces is now being fitted for burning powdered coal and it is expected to be in operation by the middle of May. Space has been left for equipping the other furnaces if the firing proves satisfactory. Burning with powdered coal is theoretically a much more efficient method of heat production than burning coarse coal. In cement burning, especially, it has proved possible to realize much of this efficiency, but in that work it is possible to allow for the introduction of the ash into the cement by adding the necessary lime. In general metallurgy the additional ash is not so easily taken care of, and in experimental work conducted some years ago by Mr. L. D. Ricketts, at Cananea, it was further found that the ash formed a blanket over the charge in reverberatories and slowed the work to a point where it was not economical. It is to be remembered, however, that the southwestern furnaces work on a high-ash coal. At Copper Cliff, in Ontario, the Canadian Copper Company, using low-ash coal from Pennsylvania, has used powdered fuel in its reverberatories with marked success for several years. At Anaconda the ash problem will be more serious than at Copper Cliff and less so than at Cananea. There would seem to be excellent promise of success, and doubtless the impetus will carry the process into other plants. In time, possibly, powdered coal will be used under boilers, but the intensity of the heat will require radical reconstruction of the fire-box from present styles.

The Mineral Resources of the Harney Peak Pegmatites—I

By VICTOR ZIEGLER

The Black Hills consist of a series of uplifted sedimentary formations dipping away radially from a central core of pre-Cambrian metamorphic and igneous rocks. The sedimentary strata represent more or less completely the Paleozoic, Mesozoic, and Cenozoic eras. The pre-Cambrian rocks are a complex of slates, phyllites, graywackes, quartzites, and a great variety of schists, cut by basic igneous rocks now metamorphosed into amphibolites. All are intruded by a much younger, but still pre-Cambrian, series of granites and pegmatites which centre at Harney Peak. Here schists are the more abundant metamorphics, while farther away the slates take their place. The more intense metamorphism of the pre-Cambrian sedimentaries near Harney Peak is probably due, as has already been pointed out by C. R. Van Hise*, to the action of the igneous intrusion.

The general topography of the region is quite rough. The granites and pegmatites when intruded in schists are eroded into picturesque, steep and castellated forms. The quartzites form usually more rounded but still steep hills. The more silicious schists and slates yield steep slopes and, when cut across the schistosity, these are exceedingly rough and craggy, while slopes cut along the bedding planes stand at 60° and 70° angles, and often practically vertical. The streams are only small but have great velocity and as a rule the valleys are narrow, often of cañon like character, and only in the vicinity of Hill City and Custer do they widen sufficiently to yield fair tillable areas.

The Harney Peak granite is rich in muscovite and quartz, and has as the important feldspars orthoclase, anorthoclase, microcline, and albite. Oligoclase and rarely biotite are present in small amounts, while apatite and zircon are the invariable accessories, at times accompanied by titanite, garnet, and magnetite. On the whole, the more typical granite is coarse in texture and shows frequent and irregular gradations into pegmatitic varieties characterized by somewhat coarser crystallization, and by the greater abundance of such minerals as apatite, garnet, tourmaline, beryl, triphylite, lepidolite, cassiterite, and other metallic minerals. In these latter types the individual crystals attain a size sometimes of one to two or even four to five inches in diameter. The granites themselves as well as the surrounding pre-Cambrian schists are cut by a great number of pegmatite dikes and pegmatitic veins. These show all gradations from a typical giant granite into well defined quartz veins. They are variable in composition, showing enrichment in a number of rare minerals and yielding economic deposits of mica, tungsten, tin, lithium, rose quartz, and rare metals, as niobium

and tantalum. Beryl, barite, bismuth, feldspar, and phosphates may prove of economic importance in the future. Some of the gold-bearing quartz veins in the vicinity of Harney Peak, also seem to be genetically connected with this granite intrusion. In the case of the Clara Belle mine the probabilities seem to be in favor of this conclusion. Gold, however, has been found by assays in some pegmatites and tungsten veins. Below is listed the principal minerals, and on the map opposite the more important mineral deposits.

Opposite is a list of minerals which were collected from the pegmatites and pegmatic veins. The letter 's' after the mineral denotes that it is of secondary origin. Those minerals starred are included as having been mentioned in the literature, but which were not collected by me. The minerals in italics are or may prove to be of economic value.

The total production from the pegmatites up to 1913

is about \$1,500,000 distributed as follows:

| | |
|------------------------|-------------|
| Mica | \$1,167,800 |
| Lithium | 143,000 |
| Tin and tungsten | 100,000 |
| Miscellaneous | 30,000 |

The Mica Deposits

Most of the important mica deposits occur in the

immediate vicinity of Custer. The position of the more important is shown on the accompanying map. The Lost Bonanza, Climax, White Spar, New York, Mc-Macken (or Crown), and Window Light mines near Custer have been the most productive in the past, while many other claims such as the Monarch, Last Chance, Warren, Crook, and also the Christianson (now Hugo), Etta, Bob Ingersoll, Wood Tin, and Everley mines near Keystone have produced smaller amounts.

The mica is muscovite of good transparency and clearness. It is usually pale rose or brown colored and known as 'rum' or 'wine' mica. This is usually faulty in that the books are commonly 'ruled' and 'wedge shaped.' By 'ruling' is meant that they possess an extra cleavage about perpendicular with the basal cleavage, which causes the mica sheets to split up into thin narrow ribbons. Wedge structure is caused by the thinning out of the foliae in one direction between cleavage planes, yielding wedge shaped sheets instead of those of uniform thickness. The properties about Custer yield the best mica and some good sheet mica has been obtained here. Practically nothing but scrap mica has been produced by the deposits near Keystone. Nearly all pegmatites are intruded with their longer diameter parallel to the schistosity. A number such as the Etta, Peerless, Hugo, Wood Tin, Tin Queen, Amblygonite, and others are roughly equidimensional in shape. The deposits near Custer have been described so admirably by Sterrett† that little can be added to his description.

The mica-bearing pegmatites are mainly coarsely crystallized quartz and feldspar, the individual masses often being several feet across. Large crystals of black tourmaline, irregular masses of blue apatite, and white or green beryl are also present. The muscovite occurs in crystal aggregates spoken of as books, which average about 6 inches in diameter, but occasionally reach a maximum diameter of 2½ or 3 ft. These usually occur in irregular segregated bunches or streaks along the contacts. Frequently they are so spaced that their cleavage planes are perpendicular to the walls, while in some cases the black tourmaline crystals with which they are associated have their longer axis in the same position. Such an arrangement is noticeable in the New York, the Bob Ingersoll, the Everley, and the Hugo mines as well as others. The muscovite also occurs in irregular shoots or pockets distributed through the dike, but even these are more liable to occur close to walls, and in these the books are liable to be of smaller size. The muscovite zones are especially regular and well defined along both sides of the dike of the New York mine.

While the individual mica books in the pegmatite near Custer average larger in size than those near Keystone, the other minerals of the pegmatites in the latter locality, with the possible exception of tourmaline,

greatly exceed in size those from the former. It is also true that practically all of the mica-bearing pegmatites near Custer are very persistent in length and form distinct dikes or elongated lense shaped bodies. Most of the important dikes are narrow, varying from 8 to 25 ft. in thickness. Near Keystone the pegmatites yielding mica are more prone to be irregular stocks or thickened and shortened lenses, attaining a thickness of 100 ft. and more. About Custer accessory and rare minerals are absent in the mica dikes, while about Keystone they are prominent. Tourmaline and apatite are present in about equal proportions in both districts. Spodumene, triphylite-lithiophylite, amblygonite, beryl, columbite-tantalite, wolframite, cassiterite, and lepidolite are absent from most of the mica pegmatites near Custer, although in some others they occur in small amounts. They may be found in most of the pegmatites about Keystone and often in some abundance. Fluorite is very rare and has been found in only one pegmatite near Keystone.

Mica has been produced somewhat spasmodically since 1879. The table below gives the approximate production only, as no definite information is available, but on the whole is believed to be nearly correct. The value has fluctuated as follows: sheet mica from 7.2 to 33.3c. per lb. Scrap mica from \$9 to \$16.71 per ton.

| | |
|-----------------|-------------|
| 1879-1884 | \$ 450,000 |
| 1885-1898 | 80,000 |
| 1899 | 1,800 |
| 1900 | 46,500 |

| 1903 | 10,000 |
| 1904 | 3,000 |
| 1905 | 5,000 |
| 1906 | 5,000(?) |
| 1907 | 120,000 |
| 1908 | 104,000 |
| 1909 | 100,000 |
| 1910 | 87,000 |
| 1911 | 90,000 |
| 1912 | 5,000 |
| 1913 | 10,000 |
| Total | \$1,168,700 |

From 1907 to 1911 inclusive South Dakota was second in the United States in the production of mica, mainly due to the activity of the Westinghouse Electric Co. which developed several of the more prominent mines near Custer and especially the New York, White Spar, and Climax mines. In 1912 the Company closed the mines and in that year produced mica only from material on the dumps. The greater part of the production of 1912 and 1913 represents rough mica shipped from mines near Keystone. Renewed activities are assumed for the Custer district for the coming year, as several contracts have been made for mica and as foreign capital has become interested in developing several claims. With some trivial irregularities mining for mica is done consistently but in a small way near Keystone. The mica is shipped in the rough, mostly to Chicago.

†Sterrett, Douglas B., U. S. Geol. Surv., *Bull.* 380, pp. 382-397, 1909.

Tin Deposits

IN THE HEART OF THE HILLS.

capacity were put up near Hill City and Keystone, and equipped with costly machinery before much was known regarding the amount of tin ore actually available.

Five thousand tons of ore was broken down without an attempt to keep it separate from a number of different prospects, and was milled in 1892, yielding only $\frac{1}{4}\%$ metallic tin.¹ The general impression throughout the Black Hills is that the operations of this Company were directed, to say the least, in a thoughtless manner. The concern went into the hands of a receiver in 1894 and its properties were tied up by the courts until 1909, when the Pahasa Tin Mining Co. was organized, which took over the holdings of the Harney Peak Tin Co. A number of claims had been meanwhile allowed to lapse, and examinations showed that the tonnage of tin ore available would not make it advisable to resume operations on the scale demanded by the mills and equipment of the defunct Harney Peak Tin Co., or by the capitalization of the Pahasa company, hence the new Company refused to consider further operations and at present is selling off the equipment, and the various claims still in its possession.

There are in this district many tons of easily mined tin ore which will average $1\frac{1}{2}\%$ of tin and which would repay mining operations conducted on a small scale. The salvation of the district lies in one of two things. As has been pointed out by Hess,² a central milling plant doing custom work, would allow a great number of prospectors to take out the small amounts of tin ore available in their claims, and could also be equipped so as to handle the wolframite ores, and possibly columbite and tantalite. There is no doubt but that a thorough sampling of a number of claims will prove that a small concentrating mill—one of 20-ton capacity—will easily pay for itself and yield a handsome profit besides. The tonnage available is too small, however, to think of maintaining plants of 250 to 300 tons capacity, as has been attempted. On the whole, the activity of the Harney Peak Tin Co. is to

be regretted, as it has done nothing but hinder the natural development of the tin deposits, and through its failure has, to a large extent, brought them into disrepute.

Tin in the form of disseminated cassiterite occurs in most of the pegmatites north and west of Harney Peak. They may be grouped in two districts, centring at Keystone and Hill City respectively. The deposits near Keystone attracted attention first, and more especially the Etta Knob, where the Harney Peak Tin Co. erected a mill costing \$235,000. As far as I was able to ascertain, there is probably as much tin in the Peerless, Hugo, Bob Ingersoll, Wood Tin, Cobalt (Margaret), and some other claims, as in the Etta, and the tin resources of all together would not warrant the erection of such a plant. The Etta deposit carries in addition to cassiterite, a secondary tin mineral, cuprocassiterite, a hydroxide of tin and copper, which is only known from this locality. This is malachite, green in color, has a dull to waxy lustre, and occurs as a staining or as a coating in veinlets. It is formed by the oxidation of stannite (the copper-iron-tin sulphide), which occurs in very small amounts in this pegmatite.

Most of the prominent pegmatites in the Keystone district are thick, stocky lenses or irregular cone-like masses. They are characterized by excessively coarse crystallization and by an enrichment in lithia and beryllium minerals. Thus individual masses of quartz and orthoclase four and five feet across are common. Amblygonite nodules weighing over 1000 lb. occur in some pegmatites, as the Hugo, Peerless, and Bob Ingersoll. Beryl, albite, apatite, triphylite, lepidolite, graphite, and tourmaline occur in masses two to three feet across. Spodumene occurs in crystals like logs, often four to five feet in diameter and over 30 ft. in length. Such giant spodumenes are further mentioned in the summary of lithia deposits. Occasionally milky quartz masses are 20 or more feet wide.

The cassiterite occurs only rarely in coarse masses, or well defined crystals, but usually as pepper tin mixed with little wolframite and fair amounts of columbite and other rarer niobates, such as tapiolite and struverite, disseminated in mica-quartz aggregates which come in irregular pockets in the pegmatites. These aggregates are irregular in distribution and oc-

SHAFT HOUSE, MOHAWK MINE, HILL CITY.

²Hess, Frank L., *U. S. Geol. Surv. Bull.* 380, pp. 131-163, 1908.

currence. They seem to favor the contacts. They are usually of small extent. In appearance they suggest a 'greisen' and they are frequently and incorrectly spoken of as such. At times such greisen-like rocks occur in segregations about the spodumene logs, as is well shown in the Etta mine. It may, however, be said safely that the pockets are so restricted and so spasmodic in occurrence that they will probably never be important as sources of tin. The only way in which such ore can ever be utilized commercially is by recovering the tin ore incidentally in the mining of some other minerals. Many tons of good ore could be secured while mining lithia minerals or mica, and some of the foresighted miners in this district are storing up their tin ore in the hope that a future demand may arise due to the establishment of a custom mill. One other objection to the ore of Keystone district, and more especially that of the Etta Knob, is the common association of cassiterite with iron minerals such as columbite, tantalite, struverite, and tapiolite, which will cause impure concentrates. Electro-magnetic separation will probably afford an easy solution of this difficulty.

The more promising tin deposits occur in the vicinity of Hill City and follow in general the course of Spring creek southward and northeastward, as may be seen from the accompanying map. These are almost always in the form of well defined dikes and veins or in highly elongated lenses. The more promising deposits are narrow and veinlike. The large and thicker dikes, such as the Sally Cavanaugh, Coates, Tin Belle, are pegmatitic in character, but they are fine grained, furnishing a marked contrast with those near Keystone. Albite, muscovite of pale green color, and quartz are the most prominent minerals. The individual grains are one-half inch or less in diameter. The muscovite is usually well crystallized, and occurs in especially fine prismatic crystals at the Coates claim. Lepidolite occurs rarely, as well as black tourmaline and fine red and brown garnets (almandite and spessartite). Orthoclase, microcline, and oligoclase are only of very minor importance. Columbite in small amounts is almost universally present. The cassiterite in the larger dikes is black and shiny metallic, frequently prismatic. It usually appears in shoots or pockets which are free from albite. In most cases the whole of the dike would be unsuitable as an ore, but it is certain that in a number of cases there are in sight several hundred tons of good ore, which would easily repay a prospector for a season's work. On most of these pegmatitic dikes little work beyond that required for assessment has been done. There are some notable exceptions, however. The Coates mine has been opened by an incline shaft to a depth of 350 ft. The Snowshoe claim has a tunnel 500 ft. long. Small tunnels are on the Tin Belle and the Tin City claims.

The tin-bearing rock in the other cases, as for example the Cowboy, Cassiterite, Tin Boom, Mohawk, and several other deposits, appears to be a gradation

toward a quartz vein. These are rarely over three to four feet in thickness and are up to 500 to 600 ft. long. They consist of an aggregate of medium-grained quartz and muscovite, frequently with much graphite, and rarely with columbite and wolframite. The muscovite appears to be a sericite variety, and favors, together with the graphite, streaks and seamlets in the quartz along which the cassiterite occurs. The cassiterite in such veins is usually of reddish brown color, and in fairly coarse grains. The Cowboy mine, opened by the Harney Peak Tin Co., shows a lens-like vein 340 ft. long, 300 ft. deep, and from 2 to 4 ft. thick. It is opened by inclined shaft and drifts to the 300-ft. level. A number of similar veins occur about a mile north of the Cowboy, and slightly west of Hill City, chief of which are the Tin Boom, Cassiterite, Mohawk, and Annie. Most of these veins show a quite variable strike, but generally in a northwesterly direction. The majority show a trough-like structure pitching down northwestward. Four such have been observed. This spot appears to be a centre of folding and faulting, and it may be that the veins of one claim are repeated thus in another. Several of these are opened by shafts sunk by the Harney Peak Tin Company.

In practically all of these veins the cassiterite appears to be more uniformly distributed than in the larger dikes, but even here, as must be expected, the distribution is irregular to some extent. Several of these deposits, if worked on a small scale, should support a 10 or 20-ton concentrating plant for a number of years.

Most of the dikes and veins show horizontal offsets on the surface, suggesting somewhat the shingling overlap of the magnetite and pyrite deposits in the pre-Cambrian rocks of eastern North America. Whether this shingling overlap is also present following down the dip remains to be proved, but seems entirely probable, as the dikes and veins must originally have been connected with the main body of the Harney Peak granite, even if only for a short time. Such shingling overlap, not too excessive in amount, might add valuable tonnage of ore to that already in sight in these dikes, especially when we remember that the top of the veins is an especially favorable place for the presence of tin on account of the upward rising mineralizing solution in which the tin is apparently readily soluble.

There was an attempt to mine the ore at the Gertie mine, near Hill City, several years ago. A small mill and a smelter were erected and some ore was concentrated and smelted. There was difficulty in smelting, the methods not being well understood, and after a thorough examination had shown the ore to be of too low grade, mining operations ceased. It was simply another ill advised mining attempt in which a mill and surface improvements were put up before the ore deposit was thoroughly examined, and before the richness of the ore and the tonnage available was known. The total tin production has not exceeded 40 tons of concentrate. It was mainly smelted in England.

Acetylene Lamps for Metal Mines

By FREDERICK H. MORLEY

Not very many years ago the acetylene lamp was a novelty, and little practical use was made of this means of illumination. There was such a general distrust of the innovation that people were afraid to employ the brilliant light which could be so easily obtained from the burning of acetylene, and the fear of explosions kept the carbide lamp in the background for a long time. As improvements were made, and acetylene lamps came to be more generally known, they were found to be excellently adapted for use upon bicycles, so that the 'bicycle lamp' became very popular, and its use spread to other fields. The first acetylene lamps used in mines were probably converted bicycle lamps. I remember seeing one of these lamps used by a mine manager at Aspen, Colorado, about the year 1900, and at that time it was considered a great novelty. A few years later, in Cripple Creek, I purchased an acetylene mine lamp that was merely a bicycle lamp to which had been attached a heavy wire handle and pointed hook. Although somewhat heavy and awkward, it proved to be highly serviceable, but it was later displaced by the light and convenient 'cap lamp' especially designed for mine service.

Discovery and History

During the past ten years the improvements in acetylene lamps for miners have been enormous, and with the gradual dissipation of popular prejudice against them they now bid fair to monopolize the entire field of lighting for metal mines, except where electricity is used in the drifts and shaft stations. Acetylene was discovered in 1836, but it was not until 1892 that its use upon a commercial scale was made possible by the discoveries of T. L. Wilson, in the United States, and H. Moissau, in France, that calcium carbide could be manufactured by the fusion of lime and carbon in the electric furnace. This comparatively simple process was soon adopted, and the manufacture of calcium carbide became a great industry, especially at Niagara Falls, where an abundance of cheap electric power was available. The acetylene lamp was introduced into mines slowly, and with considerable difficulty, partly because of the general dislike for an innovation and partly because of the imperfection of the lamps. At present, however, a number of satisfactory lamps, especially designed for mine use, are being manufactured, and the prejudice of the miners against carbide lamps is rapidly changing into a strong demand for them.

In its general principles the acetylene lamp has undergone few changes, although great improvements have been made in the details. The essential parts of a carbide lamp are: a receptacle for water; a re-

ceptacle for calcium carbide below the water receptacle; an opening or valve through which the proper amount of water flows from the upper into the lower receptacle; and a burner through which the acetylene gas escapes. These parts have, of course, undergone no essential changes; but the lamps have been made lighter and more convenient in shape, practical attachments for carrying or hanging the lamps have been added, and extra carbide containers have been provided so that lamps may be used for eight or ten hours without refilling. To prevent the clogging of the burner by soot, the gas is filtered by passing through a wire screen and a felt pad, and extra air openings are provided in the burner to insure complete combustion. Stoppage of gas may be prevented by the use of a cleaning wire which passes through the water-tube into the carbide. With many lamps a small instrument is provided with which the burner may be cleaned if it becomes choked. In some lamps the flow of water is determined entirely by the size of the water-tube, no valve being used, so that it is impossible to regulate the size of the flame or to stop the flow of acetylene gas. In other lamps the flow of water is regulated by a valve which can be adjusted or closed when required. The modern miner's lamp is made of brass or galvanized iron, weighs from 10 oz. to 2 lb. when charged, and is provided with attachments by means of which it can be carried on a cap, on a miner's candlestick, or with a hook and chain.

A Record of Tests

Tests made at the University of Utah, in 1910, for the United States Smelting, Refining & Mining Co., showed that none of the domestic lamps then tested would burn an entire shift, the carbide being exhausted in from 4 hr. 25 min. to 6 hr. 50 min. Two foreign lamps tested burned for 8 hr. 15 min. and 11 hr. 30 min., respectively, on one charge of carbide. By means of extra carbide containers, the American lamps can be used for an entire shift. The lamps need to be refilled with water every three to three and a half hours. The results of the tests of the candle-power of certain lamps were as follows:

| | Lamp No. 1. | Lamp No. 2. | Lamp No. 3. | Lamp No. 4. |
|----------------|----------------|----------------|----------------|----------------|
| Beginning..... | | | | |
| 1st hour..... | 15.60 | 2.94 | 5.05 | 9.40 |
| 2nd hour..... | 15.80 | 3.18 | 5.15 | 10.60 |
| 3rd hour..... | 16.80 | 2.95 | 5.29 | 2.96 |
| 4th hour..... | 17.80 | 2.53 | 5.27 | 0.76 |
| 5th hour..... | 14.95 | 4.30 | 3.13 | ... |
| 6th hour..... | 10.45 | 2.80 | 2.11 | ... |
| 7th hour..... | 10.25 | ... | ... | ... |
| Average | 14.52 | 3.11 | 4.17 | 5.93 |

The lamps tested were the Wolf, Baldwin No. 39,

Seranton, and Baldwin No. 32, in the order given. When candles were tested it was found that the average candle-power delivered was 0.85 per candle. Although the candle-power of most of the lamps is fairly low, yet even the smaller lamps give as much light as four or five candles, and the light can be accurately thrown upon the place where it is needed. Since the miner wants a good light at a certain spot, rather than a general illumination, the acetylene lamp offers great advantages in this respect alone. Large lamps for the illumination of stopes have been used in some mines with varying success.

In order to ascertain the extent to which acetylene lamps have replaced candles in metal mines, and to obtain the opinions of mine operators regarding the relative merits of the two forms of lighting, the manager or superintendent of 21 of the principal metal-mining companies of the United States was asked to give his experience with carbide lamps. These opinions are so interesting and instructive that many of them are given below in full. At seven of the properties, acetylene lamps are in general use, and in the remainder they are used to a limited extent. In six of the mines, tests are being conducted preparatory to equipping the mines with lamps as soon as a wholly satisfactory lamp can be secured.

The objections to acetylene lamps are numerous and varied, but many of them can be traced to prejudice and the dislike of an innovation. However, the principal valid objections seem to be: the offensive odor of the gas; the fact that many of the lamps are unhandy for general use; the time lost in filling, cleaning, and regulating; the likelihood of damage to the lamps due to falls, and the difficulty of keeping them in working order. There is a very general complaint that the lamps get out of order too easily, thus causing much loss of time. In many mines carbide lamps are used only by skilled men, such as the superintendents, foremen, bosses, and surveyors.

Disadvantages of Lamps

One mine superintendent in Nevada writes: "From my own experience with acetylene lamps, I have not dared to issue lamps to all the men working underground, as a slight fall or careless handling is apt to put the lamp out of business for some time, or possibly permanently. This would mean that too much time would be lost by the miners in repairing their old lamps or in hunting new ones." The manager of a large Cripple Creek property says: "Acetylene lamps have not as yet displaced candles to any appreciable extent in this mine. Our reason for not using acetylene lamps generally is that so far we have not found a lamp that is perfectly satisfactory. All those we have tried, get out of order too easily, and thus provide the men with an excuse to waste time in fixing or refilling their lamps." In addition to the objections quoted, several operators have found that in many of the mine lamps the gas cannot be turned off, nor is there any means for regulating the size of

the flame. The usual type of lamp has the disadvantage that it cannot be carried on the cap and cannot be stuck into a timber or rock like the ordinary candlestick, but this objection has been overcome by many manufacturers who are now supplying cap lamps and lamps with candlestick attachments.

Advantages of Lamps

In some of the largest metal mines acetylene lamps have been in general use for several years, and have given perfect satisfaction. With regard to the Homestake mine, T. J. Grier writes: "We substituted acetylene lamps for candles about three years ago, and all of our 1025 miners working underground are now using lamps. Allowing for reasonable fluctuation in market prices of illuminants, candles cost about four times as much as carbide. Properly adjusted, the acetylene lamp is less injurious to the health of the operative than smoke from candles. In the big stopes large carbide lamps are used which light up the space remarkably well, facilitating the work and making it possible for the miner to see and avoid rock coming down the slope of the pile at which he may be working." L. S. Cates, manager of the Ray Consolidated, says: "There is no question but that there is a marked increase in efficiency in our workmen due to the use of acetylene, as the illuminating power of the carbide lamp is far in excess of candles. This was forcibly demonstrated recently when one of our carbide shipments was delayed and the miners had to use candles. They complained bitterly while this condition lasted." Out of the 1400 men employed underground at the Ray, 1200 are using carbide lamps. In the property of the Osceola Consolidated Mining Co., all of the 625 miners use lamps, and the use of candles or oil was abandoned years ago. The management believes that the general efficiency of the working force is materially increased by the use of lamps, and there are fewer accidents because the working places can be readily examined and made safe. At the United Verde mine, 575 of the 600 miners use carbide lamps. W. L. Clark, the manager, says: "We have been using various makes of carbide lamps underground for the past two years. Until recently, however, we have not been able to get a satisfactory lamp for our timbermen and have adhered to the candles. We are now using the regular carbide lamp with candlestick attachment, which seems to work out satisfactorily for this class of labor, and many of the miners also prefer the candlestick attachment. For shovelers and carmen we use the Wolf chain lamp, and this lamp is also used by all other employees working where there is much draught." In the Bunker Hill & Sullivan mines, 208 of the 460 men employed underground are using acetylene lamps. The manager of this property, Stanley A. Easton, says that "the efficiency of the miners certainly increases by using carbide. We greatly prefer acetylene lamps to candles because of the lessened danger of fire. Underground fires in mine timbering are generally caused by snuffs and burning candles

carelessly left by the workmen." In the mines of the Ohio Copper Mining Co., where 96 men are employed underground, 37 are using acetylene lamps. The superintendent, F. E. Turner, writes: "We have increased our efficiency very materially; and at the same time have lowered our cost of illumination, by the use of these lamps. Most of the men who use the lamps have to travel about the mine considerably. They can get around faster and more easily with the lamp, as it gives more light than several candles would, and the light is as good while moving as when standing still. As it will burn brightly in places where there is bad air, where a candle would not burn, men using the lamp might work in such places." This last, of course, is a serious objection.

The Test of Experience

The following table gives the essential data regarding the cost of acetylene lighting in ten of the large metal mines whose managers furnished detailed information. In eleven other properties carbide lamps are not in general use, so accurate figures could not be obtained.

| Name of company | Number of men employed underground | Number using lamps | Carbide consumption per lamp, oz. shift | Cost of carbide, per lb., cents | Cost per lamp shift, cents | Cost of candles per shift, cents |
|----------------------------|------------------------------------|--------------------|---|---------------------------------|----------------------------|----------------------------------|
| Homestake Mining Co. | 1025 | 1025 | 8.0 | 3.50 | 1.75 | 7.00 |
| Ray Con. Copper Co. | 1400 | 1200 | 9.9 | 4.50* | 2.50* | 5.00* |
| Quincy Mining Co. | 1389 | 575 | 6.7 | 3.50* | 1.46* | ... |
| Oseola Con. M. Co. | 625 | 625 | 6.0 | 3.50 | 1.38 | ... |
| United Verde Copper Co. | 600 | 575 | 6.5 | 3.50 | 2.23 | 5.40 |
| Bunker Hill & Sullivan Co. | 460 | 208 | 7.0 | 5.25 | 2.30 | 6.18 |
| Calumet & Arizona M. Co. | 1000 | 60 | 7.0 | 5.50 | 2.40 | 6.64 |
| Ohio Copper M. Co. | 96 | 37 | 8.0 | 5.80 | 2.90 | ... |
| Nevada Con. Copper Co. | 200 | 20 | 4.0 | 4.67 | 1.12 | 3.27 |
| Mammoth Copper M. Co. | ... | 12 | 10.0 | 5.86 | 3.66 | 5.15 |
| Average | ... | ... | 7.22 | 4.76 | 2.17 | 5.52 |

*Estimated.

It is interesting to note that acetylene lamps are in general use in most of the copper mines, and that other mines have been slow to adopt this means of illumination. In many of the gold and silver mines lamps are being tested or are used only by superintendents, foremen, and surveyors, according to reports received from such mines as the Yellow Aster, Camp Bird, Iron Silver, Tomboy, Liberty Bell, Portland, North Star, Tonopah of Nevada, and others.

The choice of a particular style or make of lamp depends largely upon the use for which it is intended, and upon the experience and judgment of the individual mine superintendent or foreman. The large 'whole shift' lamps, with chain and hook attachment, are usually preferred for carmen and shovelers and for the illumination of large stopes. The small light 'cap' lamps are satisfactory for general use, and the

same lamps with candlestick attachment are well adapted for use by timbermen and miners working in stopes. Extra carbide containers have to be furnished with the smaller lamps. The large Wolf lamp seems to be commonly preferred where a general illumination is desired. The lamps most generally adopted are those known as the Baldwin, Maple City, Justite, and Wolf. The prices vary from about 65c. for the small domestic 'cap' lamps to \$3.75 for the larger imported lamps. Medium-weight lamps of strong construction, designed for superintendents or foremen, cost about \$2 each. All lamps are provided with reflectors of sheet metal or brass, nickel plated on the inside surface, that serve to concentrate the light very effectually. These reflectors are from 2 to 6 inches in diameter.

General Conclusions

In conclusion, it may be said that the principal objections to the acetylene lamp are as follows:

1. Lamps will burn in bad air, thus exposing the miners to a danger which would be avoided if candles were used.
2. The first cost of equipping a mine with carbide lamps is high, involving a large additional expense.
3. Lamps may be injured or broken by careless handling or falls of rock, so that the cost of repairs and renewals may be an important item.
4. Much time may be wasted by the miners in filling, cleaning, and adjusting their lamps, or in replacing damaged lamps.

The advantages resulting from the use of lamps in metal mines are numerous and marked. The most important points in favor of acetylene lighting are:

1. Lamps are not as smoky as oil or candles, and acetylene is not deleterious to the health of the miners.
2. Since they are not easily extinguished, acetylene lights can be used most advantageously in wet and drafty places where a candle could not be kept burning, and by men who have to move about a great deal.
3. One small carbide lamp gives more light than four candles, and the light can be concentrated upon the spot where illumination is most needed.
4. On account of better illumination, the working places can be easily examined, with the result that there are fewer accidents from falls of rocks.
5. The danger of fires in mine timbering is greatly lessened when lamps are used.
6. The cost of acetylene lighting per man per shift is very low, being about one-third of the cost of lighting by means of candles.
7. The use of carbide lamps results in a material increase in the general efficiency of the underground working force.

Vertical depths of shafts at the Calumet & Hecla copper mine, Michigan, are as follows:

Bureau of Mines Building

Plans for the proposed \$500,000 experiment station of the United States Bureau of Mines at Pittsburgh, have been approved by the commission appointed by Congress for that purpose. The federal government now owns the property upon which will be erected a group of buildings, especially designed and adapted for the carrying on of the mine safety work and other investigations in which the Bureau of Mines is interested. Congress a year ago, in the public buildings bill, authorized a new home for the Bureau of Mines to cost \$500,000. It is now expected that Congress, in its present session, will make a specific appropriation so that construction work may begin. It is hoped that contracts may be let by July 1. The Director is hopeful that the buildings may be completed in the fall of 1915, when they will be dedicated with suitable ceremony, including a second national mine safety demonstration, similar to that held at Pittsburgh, 1911.

The commission which has approved the plans consists of J. A. Holmes, D. C. Kingman, chief of engineers of the United States Army, and O. Wenderoth, supervising architect of the Treasury. The state of Pennsylvania has appropriated \$25,000 for coöperation in establishing this experiment station and has appointed a state commission consisting of James E. Roderick, chief mine inspector; W. R. Crane, dean of the mining department, Pennsylvania State College, and W. H. Caverly. This latter commission has tentatively approved the plans.

The buildings which will constitute the experiment station of the Bureau will form a part of a most remarkable and unusual group of monumental edifices devoted to educational purposes. On one side the Bureau's buildings will face the great group of structures of the Carnegie School of Technology. On another side is the Carnegie Institute, in which are the art gallery, museum, and library. Nearby is the imposing pile of buildings of the University of Pittsburgh. Other nearby buildings are the Memorial Hall, Pittsburgh Athletic and University Clubs, and the Hotel Schenley. The site consists of nearly twelve acres of land, part of it on the higher level of the city streets and part of it on the level of the B. & O. railroad, which railroad will furnish adequate facilities for passengers and freight traffic.

The group consists of three main buildings facing

Forbes street and the several street-car lines from the uptown district. The central building of the group, the mining building, will be three stories in height, flanked by two main buildings, one the mechanical and the other the chemical building. In the rear of these and inclosing a court will be the service building. Beyond the service building and spanning what is known as Panther Hollow and thus connecting the Bureau of Mines buildings with the Carnegie Schools, will be two buildings over the roofs of which will pass the roadway from Forbes street to the Carnegie School buildings and Schenley park.

Between the main group and the power and fuel group will be the entrance to a series of mine shafts. One of these will be used as an elevator to carry heavy material and passengers from the lower level to the upper; another will be for tests of hoisting ropes and similar mining appliances; another will be an entrance to tunnels extending under the buildings and in which mining experiments, such as fighting mine fires, will be conducted. The portion of Panther Hollow above the Power buildings will be arranged as a miners' field, the slopes of the ravine being utilized as an amphitheatre which will accommodate 20,000 spectators who may assemble here to witness demonstrations and tests in mine rescue and first-aid.

The main or mining building will contain the administrative offices, and those of the mining force. In it will be an assembly and lecture hall, a library, and smoke and other rooms for demonstrations and training in mine rescue and first-aid. The mechanical building will be for experiments and tests of mining machinery and appliances and the chemical building for investigation and analyses of fuels, explosives, and various mineral substances.

The buildings now used by the Bureau of Mines as an experiment station at Pittsburgh were loaned to the Bureau by the War Department as an emergency measure when the Bureau was created. The War Department has suggested that it now needs these buildings and it is felt the Bureau cannot retain possession much longer. The buildings are very old and are entirely unsuited to the needs of the Bureau of Mines work. It is said that the investigations have been seriously handicapped by the inadequacy of the structures now in use.

Charcoal Burning for Prospectors

By W. H. WASHBURN

Fuel for tool sharpening and blacksmith work is often an item of considerable expense in the development and operation of mines in isolated districts, where transportation costs are necessarily high. Where suitable timber is available charcoal made on or near the premises is generally used, and is an excellent fuel for this purpose. It is usually burned in heaps (called pits) covered with earth, or in ovens, or kilns, where the demand and conditions warrant the expense of building them. Besides these well known methods, that of burning it in the tree, seems to be not so well known or understood, though it is well adapted to locations where the timber is large enough for the purpose.

While the larger trees may be more economically made into charcoal in this way, those as small as 2 ft. in diameter may be used, with good results; though it would prove more economical to burn several of these at the same time, or at least as many as could be attended to by one man at a time. The tree selected should be sound, and free from wind-shakes, or other flaws, that would allow the fire to find its way to the outside, as about three or four inches of this part of the tree must be preserved to take the place of a kiln, to keep the air from the burning charcoal, except what is admitted under control, through the holes hereafter described. It should be so felled that it will lie about 1 ft. or more from the ground, if possible, so the horizontal holes may be conveniently bored. The top of the tree is also usually left on for this reason. The first hole, about 2 in. diameter, is bored vertically from 3 to 4 ft. from the butt, and to a depth equal to two-thirds the diameter of the tree. If this hole is bored too close to the butt, the fire will eat through, and necessitate banking it up with earth, which is sometimes a troublesome job. A continuous row of holes is then bored of the same size and depth, from 2 to 3 ft. apart, along the tree as far as it is suitable for charcoal.

A corresponding number of holes are bored horizontally, from both sides, to intersect the bottom of the vertical holes. After these holes are all bored, they may be fired, beginning at the butt, by inserting a piece of lighted candle, about an inch long, in a split splinter of pitchy dry wood, lowering it carefully to the bottom of the hole, and adding more splinters until the fire is well started. Repeat this process until all the holes are fired, adding a few splinters here and there to those that seem to need them, to give them all an equal start. They are then allowed to burn about six or eight hours (depending on the size of the tree, and the nature of the wood), care being observed to prevent the fire from burning the holes at their outer ends, for about 3 or 4 in. to deform them, so they could not be tightly plugged. The bark must not be relied on

for this purpose, as it burns too freely to be easily controlled.

A number of plugs should be on hand, ready to plug each hole when necessary to control the fire, and prevent it from eating away the outer end of any of them. Should this happen, however, at any time in the operation, it will be necessary to bank it up with earth, which will have to be held in place against those that are horizontal, by small cribs of boards or shakes. This bother is well worth avoiding, however, by careful attention to each individual hole; plugging those that seem likely to burn through, until the fire is under control, when they may be opened again, though perhaps

LOG ARRANGED FOR CHARCOAL BURNING.

only partly. If they are plugged tightly, too long, so the air is totally excluded, the fire will die out entirely after a while, which is to be avoided until the time for finally plugging the holes to extinguish the fire.

The tree is allowed to burn about six or eight hours according to its size and the progress of the fire. Some of the holes will probably burn faster, and require plugging sooner than others. The object to be gained is to allow the fire in each set of holes to burn until a cavity is formed, about 6 or 8 in. diameter, depending on the size of the tree, and lined with live coals around the original course of the holes, except their outer ends in the sap wood. When this point is reached they are ready to be tightly plugged, and the accumulated heat in the tree will char the wood between them. From the time the fire is started until the holes are finally plugged, the process usually requires from 10 to 15 hours, some of them being ready to plug sooner than others, of course. After the final plugging the fires gradually die out for lack of air—while the wood is being charred. The time required for the fire to completely die out is generally about three days and nights. During this time the tree should be care-

fully watched, to guard against the fire breaking out, and perhaps consuming the charcoal before being discovered.

If more charcoal than one tree will furnish is required, others should be worked at the same time after the first one is safely started. When the fire is entirely out, the charcoal is ready for use, and may be taken out as needed by chopping away the side of the tree, as shown in the cut, leaving the remainder safely housed; unless it is preferred to remove it all, to be stored elsewhere. Charcoal properly made by this method, retains more of the volatile matter of the wood than when burned in pits in the usual way, and so is of better quality.

High Cost of Sand Shafts

One peculiarity of the Lake Superior iron region is the prevalence of thick sand overburdens. For underground mining this makes trouble in sinking shafts through the sand, especially as the material usually contains much water and is often quicksand. This has tended toward fewer shafts and more permanent construction, and has resulted in the number of concrete lined shafts sunk during recent years. At several mines such unusual trouble has been encountered in putting down wood-lined shafts, that a year or more has been consumed in merely getting through the sand to bed-rock. This was the case at the Tully mine at Stambaugh, Michigan, where the shaft twisted and caved so much in the sand that often the work "was not so far along when Saturday night came as it had been on Monday morning." At the Maas mine at Negaunee, Michigan, a wooden shaft was first attempted, using great care and doing prodigious pumping, and it is related that the caving of the surface around the shaft formed a great pit in the centre of which the timbered shaft appeared "sticking up like a smoke-stack." This shaft was at last bottomed in solid rock, but it always gave trouble by getting out of alignment so finally it was replaced by a concrete shaft, the large steel headframe being moved to one side on rollers to permit this.

When such unusual trouble is encountered in sinking a sand shaft, the cost per foot mounts into extraordinary figures. To avoid this chance of getting caught in the quicksand, many of the operators took readily to letting the contract for sinking through a deep overburden to bed rock to the Foundation Company of New York. This Company sinks concrete drop shafts by the caisson method and has a trained organization of 'sand-hogs' accustomed to work in compressed air. A concrete shaft sunk under such conditions is of course permanent and will last as long as the mine, with little leakage, and requires almost no repairing. As the work is dangerous and requires special knowledge, and also because there was no competitor in the region, the Foundation Company charged what seemed to be high prices. An ordinary price for shafts over 100 ft. deep was \$500 per foot, thus a shaft through 150 ft. of sand

would cost as much as \$75,000.

This Company is very secretive about costs and methods, but is believed to have made large profits on almost all its contracts. Outside engineers, who figured on one shaft that gave unusual trouble to the Foundation Company, estimated that the actual cost was \$50,000, while the price received for 140 ft. at \$500 was \$70,000. The time taken on this particular shaft was about eight months; so much trouble was encountered that the general opinion prevailed that the contractors were losing money. For the first four months and until the shaft was 100 ft. deep, everything went well; the estimated cost of this part was about \$50 per ft. including cost of concrete which in the thick walls was a considerable item. From 100 ft. to bed rock at 140 ft., trouble was encountered from a layer of hard pan or broken rock that proved very hard picking for the men who could only work 40-minute shifts on account of the high pressure of compressed air necessary in the caisson to hold back the water.

At this time about 14 shifts were worked per 24 hours, six or seven men going down each shift; every man worked two shifts per day and received \$4 for the 80 minutes of work. In addition several surface men and much coal were necessary, so that the cost was easily \$250 per day. So slowly did the shaft drop down that a foot a week was good progress, and for several feet the cost was several thousand dollars per foot. Even this high cost was probably lower than the amount it would have taken to sink an ordinary wood-lined shaft by pumping methods. However, as the ore body was estimated at several million tons, a good permanent shaft was a necessity.

Estimation of Gold, Silver, and Platinum By Fire Assay

By G. H. CLEVENGER and H. W. YOUNG

The accompanying chart is intended to serve as a general outline of the principal operations involved in the fire assay of ores and metallurgic products for gold, silver and platinum. It is general enough to cover the crucible and scorification method of assaying as well as all individual ideas regarding the application of these two methods.

Platinum so rarely occurs as a payable constituent of ores that ordinarily no effort is made to determine it by the assayer. On account of the increasing demand for platinum, determinations of this metal are now more frequently called for than formerly. Dewey* has described a method which is capable of giving accurate results and is particularly suited to the determination of small amounts of platinum. We have therefore indicated on the chart how this method can be applied to the determination of platinum in conjunction with the ordinary fire assay for gold and silver.

*The Direct Determination of Small Amounts of Platinum in Ores and Bullion,' Frederic P. Dewey, *Trans. Amer. Inst. Min. Eng.*, Vol. 43, pp. 578-581.

ESTIMATION OF GOLD, SILVER AND PLATINUM IN ORES OR METALLURGIC PRODUCTS BY FIRE ASSAY

ORE or METALLURGIC PRODUCT

A small representative sample
separated by an appropriate
method of sampling and ground to
the necessary degree of subdivision

Portion taken for Assay

Possible constituents of
the charge before fusion

General Classification of Important Constituents of Ores and Metallurgical Products

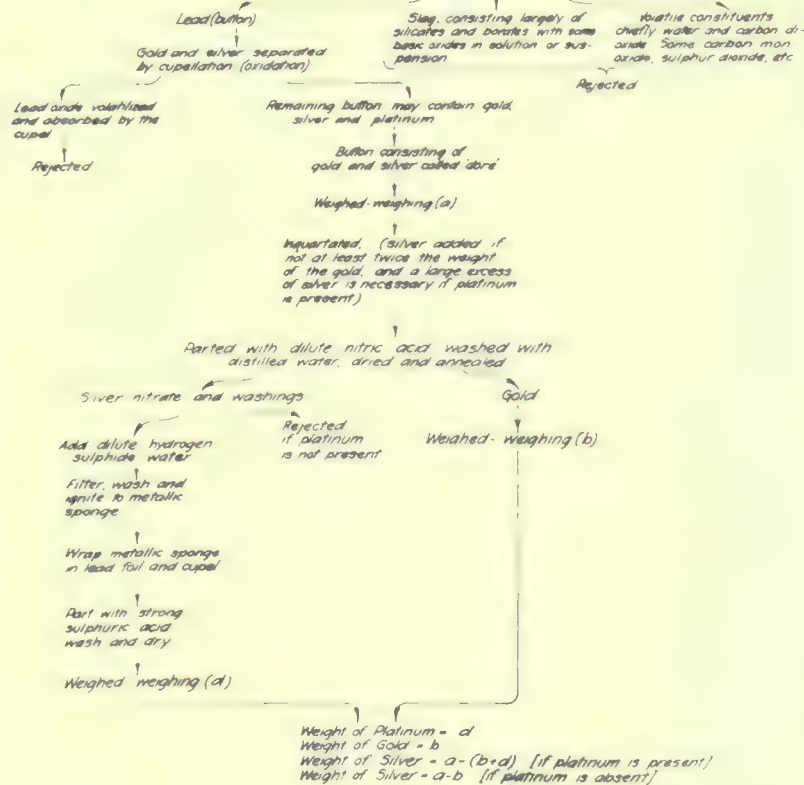

| Acids | Bases | Reducing Agents | Oxidizing Agents | Metallic and metallic impurities (bearing chiefly on classification with other elements) | Metals (sought) |
|----------------------------|--|--|--|--|---|
| Silica (SiO ₂) | Iron Oxide (Fe ₂ O ₃) Iron Oxide (Fe ₃ O ₄) Manganese Dioxide (MnO ₂) Calcium Carbonate (CaCO ₃) Magnesium = (MgCO ₃) (Alumina Oxide (Al ₂ O ₃) Sodium Oxide (Na ₂ O) Iron Oxide (FeO) Calcium Oxide (CaO) Magnesium = (MgO) Aluminum = (Al ₂ O ₃) Probably can best be con- sidered as a base in its pur- suing. Occur in ores in the uncombined condition. 2 in general occur in combination with silica | Sulphides (MS) Arsenides (MAs) Antimonides (MSb) Sulphate = (MSO ₄) Graphite (C) Probably from con- sideration in the assay | Iron Oxide (Fe ₂ O ₃) Iron Oxide (Fe ₃ O ₄) Manganese Dioxide (MnO ₂) Carbon Dioxide (CO ₂) Probably from con- sideration in the assay | Iron (Fe) Copper (Cu) Zinc (Zn) Bismuth (Bi) Tin (Sn) Cobalt (Co) Nickel (Ni) Antimony (Sb) Arsenic (As) Tellurium (Te) Selenium (Se) Sulphur (S) | Gold (Au) Silver (Ag) Platinum (Pt) |

General Classification of Fluxes used in Assaying Ores and Metallurgical Products

| Acids | Bases | Reducing Agents | Oxidizing Agents | Metals | Neutral Fluxes |
|--|---|--|---|---|---|
| Silica (SiO ₂) Fluor (Na ₂ F, CaF ₂) Sodium Silicate (Na ₂ SiO ₃) Soda Ash (Na ₂ CO ₃) Soda Bicarbonate (NaHCO ₃) | Litharge (PbO) Red Lead (Pb ₃ O ₄) Alumina Carb (Al ₂ O ₃) Soda Carb (Na ₂ CO ₃) Soda Bicarb (NaHCO ₃) | Flour Angol (MgO, Al ₂ O ₃) Starch Charcoal (C) Coke Dust (C) Barren Pyrite (FeS) Sulphur (S) Metallic Iron (Fe) | Litharge (PbO) Niter (KNO ₃) Manganese Dioxide (MnO ₂) Carbon Dioxide (CO ₂) Oxygen (O) Evolved from arsenic carbonates used. Gases in the air become active when air is admitted to the crucible. These substances are in scorification or roasting. | Test Lead (Pb) Sheet Lead (Pb) Silver Foil (Ag) | Salt (NaCl) Fluoride (CaF ₂) |

A suitable weight of ore combined with the proper proportion of appropriate fluxes and subjected to fusion either by the crucible or scorification method. In the case of assay- ing high grade bullion the operation would begin at cupellation.

Products of Fusion

United States and many foreign countries, the gold, silver and platinum are reported in troy ounces and decimals thereof per ton of 2000 pounds avoirdupois.

Certain English countries, gold, silver and platinum are reported in troy ounces, penny-weights and grains per ton of 2240 pounds avoirdupois.

Mexico and certain other countries, silver is reported in kilos per metric ton of 1000 kilos, gold and platinum in grams per metric ton of 1000 kilos.

Work at the Phelps, Dodge & Co. Properties in 1913

*As mentioned in the 'Special Correspondence' pages of this journal of April 4, this concern's subsidiary companies treated a total of 1,978,892 tons of ore yielding 155,665,712 lb. of copper, 5,701,628 lb. of lead, 32,037 oz. of gold and 2,073,376 oz. of silver in 1913. The Phelps, Dodge company received \$9,110,000 in dividends from its subsidiaries and paid four dividends amounting to \$7,425,000 during 1913.

Copper Queen Consolidated Mining Company

The separate reports of the general manager, S. W. French; the superintendent, Gerald Sherman; smelter superintendent, Forest Rutherford; and G. D. Van Arsdale in the experimental plant, contain the following information: Development in the Limestone and Sacramento Hill mines covered 92,780 and 7362 ft., respectively, while churn-drilling amounted to 10,830 ft. In the Copper King group work totaled 5141 ft. Two important orebodies have been discovered, one at the Lowell, the other in the Sacramento division. But the most interesting development, in its favorable bearing on the future of the district, has been the exposure of ore on the Wade Hampton and White Tail Deer, two claims long neglected, but members of large groups owned by the Copper Queen to the west of Bisbee. The policy of increasing reserves and carrying development work well in advance of mining has been continued, with gratifying results. The estimate of ore reserves shows a total of 2,567,928 tons of average grade and 211,199 tons of lean sulphide in the Limestone mine.

Four methods of stoping are practised, the choice depending on local conditions. The comparative costs are:

| | Tonnage. | Cost per ton. |
|----------------------|----------|---------------|
| Square-setting | 612,299 | \$2.113 |
| Top-slicing | 20,582 | 1.300 |
| Cut and fill | 58,239 | 1.400 |
| Shrinkage | 3,822 | |
| | 694,942 | \$2.028 |

Electric haulage track aggregates 9.6 miles of main line.

A compound, geared man-hoist at the Sacramento shaft has been added to the hoisting equipment. A fifth compartment is being raised at the shaft, which will be used for air mains, electric cables, etc. There will be room for pump columns when needed. The quantity of water pumped was less than usual.

The additions of two boilers and a 7000-ft. compressor to the plant at the power-house were completed as quickly as delivery of the machinery permitted, but not before they were needed.

A part of the Lowell fire country was opened a short time ago, and it was found that the 12-3-34 raise had been burned out since it was closed. Gas is not now

coming from the bulk-headed area. Work about the fire has been confined to repairing the air course to the surface. The filled and abandoned 450-50 stopes of the Holbrook have been hot for more than a year. In July there was an appearance of gas on the 600-level in which one man was overcome. The fire threatened to be serious, and would have been so but for the efforts to control it by Mr. Hodgson and his miners, who fought it heroically at the risk of their lives. Three men were saved only by artificial respiration and the use of the pulmotor. Another fire in the Czar was due to breach of rules. The eagerness with which all employees respond to the call of rescue-work and fire-fighting has been most gratifying.

Positive ventilation was introduced at the Gardner division, with great improvement in the working conditions. Both temperature and humidity have been reduced. It is believed that economy has already resulted, which will be more clearly shown in the future. Change rooms have been built at the West Atlanta and Sacramento shafts of the same type as the Uncle Sam change room. A 'Safety First' organization was instituted among the employees of the mine department, who meet regularly to discuss means for the prevention of accidents. Frequent bulletins are posted and otherwise distributed, describing accidents and recommending means of avoiding them. This department is under the energetic and intelligent leadership of W. E. McKeehan, as safety inspector for the mine and smelter, and instructor in rescue work and the use of rescue apparatus and helmets.

Bisbee Production

During the year the following tonnages of ore and slag were extracted from the mines and from old Bisbee dumps:

| | Tons. |
|---|---------|
| Shipped to Douglas: | |
| Ore | 712,444 |
| Precipitates | 603 |
| Old dump slag | 93,578 |
| Old dump slag by lease | 634 |
| Ore from lessees | 21,524 |
| Flue dust from lessees | 44 |
| Ore for experimental leaching plant | 4,765 |
| Shipped to El Paso: | |
| Ore mined by Company | 14,800 |
| Ore mined by lessees | 773 |
| Shipped to Globe: | |
| Sulphide ore | 18,316 |
| Total | 867,481 |

The ore shipped to El Paso contained 5,701,628 lb. of lead, and that to Douglas and Globe a total of 16,213 oz. gold, 919,138 oz. silver, and 97,181,725 lb. copper.

On the basis of raw ore, Moctezuma concentrates, and secondaries, there was delivered during 1913 to the cupolas and reverberatory furnaces, 1,193,726 tons. Of this total 835,093 tons was ores to blast-furnaces,

*Abstract from annual report.

161,707 tons to reverberatories, 37,556 tons to converters, and the balance, or 179,815 tons were secondaries, retreated by the various departments. The shrinkage at roasters was 20,445 tons.

The bullion produced was 134,513,330 lb., which contained: copper, 133,410,582 lb.; silver, 1,870,162 oz.; and gold, 31,141 ounces.

During the month of September, further experiments on dust losses from the large steel stack, were made, with the view to proving whether the present conditions of operation as compared with those of the year 1909 showed any difference. It was found that the copper loss had been reduced from an average per day of 14,310 to 2286 lb., with practically the same number of furnaces and converters in operation.

Flue dust from the blast-furnace department was 39,748 tons or 3.92% of the charge, against 5.90% in 1912, and 7.59% in 1911. An average of 8.08 furnaces were operated, smelting 343.5 tons per charge per day, using 12.4% coke per ton of charge. The matte-fall was 18.79%, against 20.97% in 1912. An average of 5.97 roasting furnaces were at work, averaging 56.5 tons per furnace day. Flue dust equalled 5.2% of the charge. Three new McDougall furnaces were added. An average of 1.71 reverberatory furnaces was operated, smelting 289.6 tons per furnace day. A third furnace was completed during the year. Part of the lining is of magnesite instead of silica brick. Oil consumed was 0.9 bbl. per ton of charge. An average of 6.5 basic-lined converters was operated treating 206,493 tons of matte.

During the year 12,378 samples were made and 318,507 tons of ore handled by the sample mill forces. There were 101,455 determinations made in the laboratory, of which 95,435 were for the Company and 6020 for the mines at Bisbee.

In the power-plant one 12,000-cu. ft. Nordberg compressor for use on the converters was installed. There was 86,191 bbl. of California oil used at the main boiler-plant and 161,536 bbl. at the reverberatory furnaces and roasters. The cost of a horse-power for the year was \$54.844, or slightly better than last year, and the average daily horse-power developed was 4595.8.

Improvements Contemplated

For 1914 both known and prospective changes are as follows: (1) unloading and spreading device at roaster plant; (2) one large converter stand; (3) seven more roasters, building to cover bins and conveyors, for treatment of excess sulphide ores from Bisbee; (4) skull-cracker for breaking converter slag shells; (5) protection of tracks at ore beds; (6) the erection of a copper casting furnace is under consideration; and (7) tower to remove crane trolleys.

The average number of men per day employed was 1039.

During the year an experimental plant was completed, and experiments were conducted principally with the view of determining the best method of leaching low-grade ores and the tailing from the concen-

trators. A Wedge furnace, of the muffle type, was erected, which produced calcines containing a high proportion of their copper soluble in water, and practically all of the remainder soluble in dilute acid, but with a high fuel consumption. The recovery of the dissolved copper was effected by electrolysis, using graphite anodes, and reducing the resistance and increasing the yield of sulphuric acid, by injecting sulphur dioxide into the electrolyte. The results were favorable, but several problems which presented themselves, as the experiments progressed, remain to be solved, as well as a reduction of the high fuel consumption, before definite conclusions can be reached.

Dividends paid by the Company in 1913 totaled \$5,700,000, net earnings being \$6,916,900.

Detroit Copper Mining Company of Arizona

The reports of A. T. Thompson, general manager; M. H. McLean, mine superintendent; and V. P. Hastings, smelter superintendent of this Company, contain the following notes: Development in the Ryerson, Yankie, Copper Mountain, and Arizona Central mines covered 6197 ft., and in outside mines 18,492 ft. Ore mined per foot of development was 28.583 tons. A total of 533,563 tons of ore of all classes, averaging 2.89% copper was mined from all mines. Of this, 518,718 was concentrating ore. A Nordberg compressor was installed to operate a larger number of drills, and new change-houses and other improvements were built. On the outside mines development work was continued on the Esperanza, Santa Rosa, Wattle, Fairbanks, and Summit claims, while exploration was started at the Gem, Summit No. 2, Colorado, and Antietam properties. The installation of new hoisting plants at practically all of these properties, and the enlargement of plants at properties under development, meant very high outlays during the year. Power lines were built to some of these outlying camps.

The concentrating plant treated 517,518 tons of ore averaging 2.785%, yielding 66,928 tons of concentrate containing 15.834% copper. The saving was 73.52% on the ore and concentrate, 75.18% on the ore and tailing, 74.76% on the concentrate and tailing, and 75.27% by assay only. Water used per ton of ore milled was 554.98 gallons.

The blast-furnace treated 141,094 tons of mixed products, using 16,099 tons of coke. The bullion produced was 22,255,130 pounds. For some years past the advisability of changing the method of smelting from cupola to reverberatory practice, has been under discussion, and the old smelting and power plant was not kept up to the standard of perfect repairs and efficiency. On determining to retain the old system, a thorough overhauling of the smelters, including the replacement of silicious by basic converter lining, has been carried on. In re-designing the smelter plant and improving smelting operations the officials were greatly assisted by George B. Lee.

A total of 1510 men were employed, 946 working at the mines. Net earnings for 1913 were \$1,112,870,

while during this period \$780,000 was paid in dividends to the shareholders.

Moctezuma Copper Company

This Company operates at Nacozari, Sonora, Mexico, and the general manager, J. S. Williams, Jr., reported as follows:

The total mining done during the year amounted to 31,292 ft. Of this 8582 ft. was for stoping purposes and the remainder of 22,710 ft. for development work. This is an increase of 40% over corresponding figures during 1912. Thirty-nine per cent of this development work was done in ore. Beside developing ore below the Porvenir adit large stopes of good ore have been opened on two levels in ground that had been abandoned as barren. During the year 1028 ft. of exploratory work was done outside of the Oval, but no success in finding ore rewarded us. The cost of delivering ore to the railroad bins was decreased during the year, although the total cost of mining was slightly increased. This increase was caused partly by higher hoisting costs due to handling heavier tonnage from below the 700-ft. level, but principally to increased activity in exploration and development made possible by the more general use of machine drills.

The concentrating plant treated 603,654 tons of ore assaying 3.557%, and yielded 135,057 tons of concentrate containing 13.376% copper. The tailing averaged 0.67%, and the saving, by four methods of reckoning, was 85%. Fresh water used per ton of ore milled was 1020.72 gallons. Concentrate is sent to the Douglas smelter of the Copper Queen company.

Apart from unavoidable delays, work was suspended for 58 hours on account of a battle between the federals and the state forces, and for 153 hours by a strike of the concentrator men. A series of smokers for the bosses at the mine were held during the year, at which safety measures were discussed. The results have been good. The present power line between Nacozari and Pílares is too small to carry the necessary load. A new transmission line, using heavier wires and steel poles, is in course of construction. It was considered advisable during the year to reduce the working hours of mechanics and laborers from ten to nine hours without any change in wages. Net earnings of the Company were \$2,402,447, of which \$1,950,000 was paid in dividends.

Burro Mountain Copper Company.

This Company's mine is at Tyrone, New Mexico, and the superintendent, E. M. Sawyer, reports that the Niagara haulage adit to deliver the ore from the Burro Mountain claims at the railroad terminus and to explore the intermediate ground, was driven continuously throughout the year and was the most important piece of work. This adit was advanced 3753 ft., making the total length to date 4286 ft. Connections will soon be made with the fourth and fifth levels of the Sampson mine at Leopold for the purposes of ventilation and drainage and for drawing ore from the east orebody

when stoping is recommenced. The bulk of the east orebody lies between the adit level and 180 ft. above. For 2500 ft. from its mouth, the adit passed through solid, firm ground which stands well; beyond this point the ground was somewhat heavier.

Toward the end of the year a prospect drift was driven from the main tunnel at a point about 1200 ft. from the portal and revealed a body of low-grade sulphide ore. A series of cross-cuts and raises in this ore has shown it to be of considerable importance and so far about 50,000 tons averaging 2.35% copper has been added to the known reserve. No other prospect work was done at the Chenung or Sampson mines.

A favorable site for the concentrator designed for 1000 tons daily capacity has been chosen about three miles east from Tyrone. The ample space which this site provided for storage of tailing was one of the elements which determined its selection. A central power-plant, equipped with two 1000-hp. Diesel engines will be built at Tyrone, near the collar of No. 2 shaft.

Stag Cañon Fuel Company

The coal mines are at Dawson, New Mexico, and the general manager, T. H. O'Brien, states that the production was 1,322,813 tons, a decrease of 60,749 tons from 1912. Development totaled 30,226 ft. Concrete portals have been erected at several of the main entries and manways; fire-proof overcasts were also erected, and every provision that could be foreseen was made against accidents. The explosion in No. 2 mine on October 22 resulted in the death of 256 men. The coroner's jury, which exonerated the Company from blame, was satisfied that the ignition of dust occurred during working hours through a badly directed shot, fired against the most rigid rules. The explosion was propagated exclusively by coal dust, and was of such violence that only 29 men in No. 2 mine escaped. Most of those who met their death were killed instantly. To guard against such calamities shot firing was effected by electricity only after every man was known to be out of the mine. In this case a miner connected up his charge by a long copper wire with the current of the trolley system. The coke production was 293,090 tons from 478,473 tons of coal, equal to 61.32%. Net earnings were \$362,564, and \$180,000 was paid in dividends.

Phelps, Dodge Mercantile Company

The general manager, W. H. Brophy, reported that the gross sales and transfers in 1913 were \$6,772,289, showing a net profit of 9.28%. The stores are at Bisbee and branches, Douglas, Morenci, Dawson, Nacozari, and Pílares, and the increase of sales over 1912 was \$628,933. The furnishing of supplies to troops along the border and at Fort Huachuca has also added to the volume of our business at the Bisbee store and branches. There was an average of 490 people employed at the various stores and general office.

Net earnings were \$649,518, of which \$500,000 was paid in dividends.

Cost of Erecting Treatment Plants

By M. W. VON BERNEWITZ

In view of the articles* on 'Under-Estimating the Cost of Milling Plants,' by A. Sydney Additon, the following cost of erecting two different types of mills should be of interest. The Commonwealth stamp-mill and cyanide plant, with mine plant, consisting of a crushing plant with No. 6 and No. 4 Gates crushers and revolving screen, etc.; a mill with an 18-in. belt conveyor 300 ft. long 20° incline to mill bins; thirty

automatic tramway from shaft orebins to crusher bin were estimated to cost \$310,000, divided as follows: mill complete, \$239,100; power-plant, \$35,900; and shaft and mine equipment, \$35,000. The daily capacity was estimated at 350 tons

In several instances, notably concrete work and electrical wiring equipment, the estimates have been considerably exceeded. Nevertheless, the installation as a whole will closely approximate the above estimate, as shown by the table of costs below, taken from the annual report of the Commonwealth Mining & Milling Company:

| | A Crusher Plant | B Stamp Mill | C Refinery | D Power Plant | E Mine Surface Plant | F Railway Siding | Undergrd. Plant | D Shaft Equipmt. and Timbering | |
|----------------------------------|-----------------------|--------------------|---------------|---------------------|-------------------------------|------------------------|--------------------|-----------------------------------|--------------|
| Excavation | \$ 1,156.16 | \$ 7,358.57 | \$ 653.71 | \$ 712.64 | \$ 155.39 | \$114.00 | | \$ 10,180.47 | |
| Concrete | 2,794.05 | 25,068.95 | 179.62 | 5,479.53 | 1,655.07 | | | 35,177.22 | |
| Machinery Cost | 7,530.68 | 78,735.87 | 15,100.43 | 33,283.11 | 8,860.01 | | \$10,749.74 | 156,557.90 | |
| Machinery Erection | 960.00 | 10,377.74 | | 2,569.87 | 354.20 | | | 14,261.81 | |
| Building Lumber | 1,895.65 | 13,172.66 | 121.81 | 597.76 | 703.18 | | | 22,747.99 | |
| Building Covering | 656.81 | 5,333.21 | 314.08 | 549.64 | 81.56 | | | 6,938.30 | |
| Doors and Windows | 172.61 | 1,592.07 | 84.10 | 236.90 | 64.06 | | | 2,149.74 | |
| Tramming and Erection | 538.10 | 6,723.47 | 59.90 | 276.16 | 385.45 | | | 7,983.08 | |
| Steel Tanks in Place | 1,630.56 | 8,932.48 | | | | | | 10,563.04 | |
| Wood Tanks in Place | | 9,788.79 | | | | | | 9,788.79 | |
| Steel Structures in Place | 298.00 | 365.42 | 190.57 | | 3,140.14 | | | 3,994.13 | |
| Piping Cost | | 15,577.22 | | 3,844.43 | | | 1,159.52 | 20,581.17 | |

1500-lb. stamps, arranged for coarse crushing; three 8 ft. by 30-in. Hardinge conical pebble mills; two 22 by 5-ft. Allis-Chalmers tube-mills; one 20 by 4-ft. old style tube mill (on hand); three Caldecott cones; three Dorr classifiers, latest types; two 38-ft. Dorr thickeners; nine 12 by 36-ft. agitating vats (two on hand); four 42-ft. Dorr thickeners; four 11 by 18-ft. Oliver filters; two Merrill clarifying presses; two Merrill precipitation presses; and two Donaldson melting furnaces; a power-plant with one 22 by 42 by 42 cross-compound Allis-Chalmers heavy duty Corliss condensing engine direct connected to one 750-kva., 3-phase, 480-volt generator with exciter, one C. H. Wheeler horizontal surface condenser, one 12 by 24 Pratt patent rotary vacuum pump, one 7-in. double suction centrifugal circulation water pump, one 8 by 8 vertical enclosed steam engine, direct connected to pump, one 5¼ by 3½ by 5 horizontal steam driven duplex pump, one 1200-hp. Stillwell open type feed-water heater, two 10 by 6 by 12 duplex plunger feed pumps, one 8-in. vertical steam separator, one 10-in. automatic exhaust valve, and one 4-panel switchboard complete with instruments; new 'D' shaft and surface equipment; 47-ft. steel head-frame, 100-hp. double-drum electric hoist, two 3-ton skips; two 2-deck man cages, one 1600-cu. ft. Ingersoll-Rand cross-compound Imperial type X3 compressor; air-drills and cars, telephones, etc.; new blacksmith shop, fitted with No. 5 Leyner drill, sharpening machine, etc.; Hunt

The actual work of erecting this plant was done by contract, by the Concrete Construction Co. of Tucson, Arizona, and Campbell & Kelly, Inc., of Tonopah, Nevada. The time occupied was about one year. Reckoning on a stamp basis, the cost of this mill was approximately \$11,170 per stamp. The ore, according to the annual report, will average about \$5.35 per ton.

At Kalgoorlie, Western Australia, the Associated Northern Blocks Co., in 1903, erected a new plant of 120-ton capacity. The estimate was about \$170,000. The equipment consisted of the following: head-frame, 90 ft. high; two Babcock & Wilcox boilers, feed pump, one Robey 250-hp. tandem compound engine, one 25-kw. vertical engine direct connected to a dynamo, feed-water heater, Pearn surface condenser, grease separator, main drive shaft and pulleys, and friction-clutch pulley; 400-ton orebin, No. 5 Gates crusher, and Robins belt-conveyor; three No. 5 Krupp ball-mills, Krupp screw conveyor, dust house and connections; belt and bucket elevator, orebin for fine crushed material, push conveyor, five Merton roasting furnaces, flue and stack foundation, 100-ft. steel stack and hot-ore conveyor; six Forwood-Down grinding pans, and Krupp chain and bucket elevator; one set of settlers; five 22 by 6-ft. agitators and gear, and two vertical three-throw 10 by 12-in. Pearn pumps; a vortex mixer and pump; three Dehne 5-ton filter-presses, and fourteen side-tip cars; zinc boxes, tilting furnace, amalgamating barrel, clarifying press, clean-up press, etc., and solution tanks and Sulzer pumps.

*Mining and Scientific Press, July 16, 26, August 16, 23, and October 18, 1913.

The actual cost was as follows:

| | | | |
|----------------------|----------|-------------------------|-----------|
| Mill-buildings | \$20,640 | Roasting furnaces ... | 38,900 |
| Head-frame | 8,150 | Grinding pans | \$9,700 |
| Power-plant: | | Settling boxes | 2,880 |
| Boilers | 12,960 | Agitators | 8,640 |
| Engine | 7,440 | Mixer and pump..... | 1,400 |
| Dynamo set | 2,880 | Pumps for presses... | 6,250 |
| Heater | 1,290 | Filter-presses | 15,840 |
| Condenser and cool- | | Percolation plant (dis- | |
| ing plant | 12,820 | carded) | 7,200 |
| Main shaft and pul- | | Clean-up department. | 4,900 |
| leys | 2,400 | Solution tanks | 4,950 |
| Crusher station and | | Sundries | 3,980 |
| orebin | 11,700 | General charges | 5,800 |
| Ball-mills | 12,900 | | |
| | | Total | \$203,620 |

This plant was erected by day labor under J. H. Dagger in about 150 days. Including some rich sulpho-telluride ore shipped prior to 1903, the plant has treated 365,555 tons of ore, and a large tonnage of old tailing, yielding gold worth \$8,300,000, and \$3,485,000 in dividends.

Mineral Production of Broken Hill

The year 1913 proved much better than was anticipated. The industrial trouble expected at the end of the year has not yet occurred. It looks as if the 18 months' extension of the agreement between the mining companies and unions will be accepted without further demur. If the miners and the small portion of them that cause all the trouble are satisfied not to make worry, the prospects for 1914 appear good. During last year there were two strikes which affected work generally, metals averaged a lower rate, and a water trouble caused sundry stoppages, yet the official figures show an export record in the history of Broken Hill, according to a correspondent in the *Australian Mining Standard*.

Since 1907 the mineral exports of Broken Hill have been as follows:

| | |
|------------|------------|
| 1907 | £3,081,031 |
| 1908 | 2,015,647 |
| 1909 | 2,076,574 |
| 1910 | 2,432,935 |
| 1911 | 3,100,109 |
| 1912 | 4,186,200 |
| 1913 | 4,327,217 |

One marked feature of mining operations in 1913 was that exploration at depth opened new ore, and the South, North, British, and South Blocks (Zinc Corporation) have all shown highly satisfactory results. Only a few years ago the North and South were regarded as almost worked-out mines; today they are in the forefront. The British, also, was never before in such a strong position. A comparison of the past two years' results is as follows:

| | 1912. | | 1913. | |
|--------------------------|---------|-----------|---------|-----------|
| | Tons. | Value. | Tons. | Value. |
| Crude silver-lead ore.. | 29,605 | £ 89,140 | 24,754 | £ 58,209 |
| Silver-lead concentrate. | 279,915 | 2,769,170 | 327,431 | 3,171,433 |
| Zinc concentrate..... | 433,054 | 1,320,666 | 405,740 | 1,088,313 |
| Silver-lead slime..... | 4,503 | 7,218 | 10,036 | 6,940 |
| Zinc slime | | | 1,606 | 2,222 |

Mastic Lining for Acid Tanks

In connection with the operations of the Chile Exploration Co. in Chuquicamata, Chile, there has been developed a new method of lining concrete tanks which are subject to the action of sulphuric acid. The Company's copper ores in Chile are handled by the combined sulphuric acid and electrolytic method. After the ore is crushed it is put into large tanks or vats and then leached with a 10% sulphuric acid solution for 24 hours. The solution containing the copper is led through another process for extracting chloride and then passes to the electrolytic tanks. There the copper is extracted and the remaining solution, which is now increased in sulphuric acid, owing to the copper being separated from its chemical connection with sulphur, is then returned to the leaching vats ready for extracting the copper from a new batch of ore.

It can readily be seen that the large tanks required must be such as will withstand sulphuric acid, which, of course, concrete would not do unless provided with a protective lining. Experiments with tanks of various types were made, but in most instances proved failures. It was then suggested that an especially prepared acid-proof asphalt mastic lining might be used to overcome the difficulties encountered. In coöperation with E. A. Cappelen Smith, consulting metallurgical engineer for the Chile Exploration Co., experimental tanks, among them one 15 ft. high, lined with Trinidad asphalt mastic were built at the research laboratory of the A. S. & R. Co., at Maurer, New Jersey. With these tanks there was duplicated as nearly as possible the operation of extracting copper as it is carried out in Chuquicamata.

Under the direction of Mr. Smith, various other materials were also experimented with at Maurer, but they all proved unsuitable, with the exception of the asphalt mastic. It was on the strength of this material having shown no defects or deterioration after a year's test that the Chile Exploration Co. has placed the contract for lining with asphalt mastic some 150 concrete tanks or vats from 15 to 16 ft. in depth and from 120 to 150 ft. in exterior dimensions. The lining of these tanks in Chile will require from 1250 to 2000 tons of asphalt mastic, which is being prepared here and shipped to Chile. The first cargo of 500 tons was shipped in February, and as soon as it arrives, which will take about three months, as the ship has to go around the Horn, an experienced superintendent and nine mastic workers will be sent to Chile to do the lining of the tanks. The experimental work at Maurer, the preparation of the asphalt mastic, and its application to the concrete tanks was conducted by Henry Wiederhold, manager of the Vulcanite Paving Company.

The Aramayo Francke mines, Bolivia, produced in January 313 tons of black tin, 23 tons of copper, and 24 tons of silver ore.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Rand Banket

The Editor:

Sir—Permit me to congratulate you on the publication of this excellent series of articles, together constituting a treatise on a subject of immediate interest. Even to those having no first-hand knowledge of the mining geology of the Witwatersrand it has been evident that in the ascertainment of the real structure of the pyrite 'pebbles' would be found the key to the origin of the gold in the conglomerate. Becker recognized this in his able summary of the knowledge extant at the time of his visit to the Rand. De Launay also was 'bunkered' by the "rolled pyrite" and the "pebbles of pyrite."¹ Even after two decades of active mining, punctuated by the scientific investigations of sundry distinguished geologists, the origin of these remarkable deposits remained hardly less obscure. In 1907, J. W. Gregory, in his valuable paper on the subject, happens to quote from an editorial article by myself in the *Engineering and Mining Journal* of October 17, 1903, in which I stated that "the origin of the banket still remains the great riddle of modern economic geology." It is true, by that time the placer and the precipitation theories had lost support while the infiltration or lode theory had gained ground, but so long as the 'pebbles' of pyrite remained unexplained, one theory was as doubtful as the other. Despite the early advocacy of the lode theory by J. S. Curtis, followed by a number of mining engineers then resident in South Africa, the riddle remained unsolved. Gregory endeavored vainly to prove that "the placer theory best explains the facts." To explain those facts he had to trespass on the scientific credulity of his hearers. The effect was unconvincing. He also ran against the 'pebbles' of pyrite, only to reject the notion that they were of "concretionary origin." On the contrary he concluded that they were of alluvial character, despite the suggestions, already published, both of Hatch and of Horwood, that they were among the things that "are not what they seem." To the discussion that followed Beck contributed a comment that was brief, but intensely effective; and Maclaren rebutted an argument of Becker's that previously had been a real obstacle to any ordinary lode theory. Becker argued that a conglomerate was less porous than a sandstone, because the interstices of the former would be filled with fine sand, but Maclaren suggested that this involved the assumption, not warranted, that the inter-

stitial sand of the conglomerate was identical in character with the mass of the sandstone, and that the interstitial spaces within the sandstone had not themselves been filled with finer silt.² The filling between the pebbles of the banket consists of fairly large grains of quartz with heavy minerals, while the sand of the enclosing quartzite was deposited with mud and felspathic material, the latter appearing now as kaolinite and sericite. Thus the sand, by pressure, became impervious, while the matrix of the conglomerate "protected largely from pressure by the bridging of the larger pebbles"—as Maclaren aptly phrased it—remained porous and percolable. This helps to explain why the gold-bearing solutions enriched the conglomerate and avoided the intermediate layers of sandstone. It also gives a clue to the reason why the richest ore is now associated with large pebbles. Kuntz drew attention to the fact that not only is the gold restricted to the cement between the pebbles, but that the banket is barren where the interstices between pebbles are filled with sand. The fact that the gold is not concentrated along the former bedrock—now the foot-wall—and that the narrow seams of banket are richer than the wide ones is suggestively against an alluvial origin. Moreover, the effects of dikes and faults in modifying the distribution of the gold and the pyrite associated with it are dead against the 'fossil placer' theory or its ingenious modifications.

One reason why the ordinary lode theory, of infiltration by gold-bearing solutions circulating along the porous beds of conglomerate found so little favor was because it was deemed desirable to mark the Rand deposits as unlike anything else of the kind, as an occurrence beyond the ordinary experience of mining. Either the placer or the precipitation theory, with that hybrid born of an unnatural union between the two of them, namely, Gregory's idea of solution with re-deposition, was regarded in a kindly way because it labelled the Rand as 'extra-ordinary.' Thus Gregory argued that, according to the placer theory, no impoverishment in depth need be anticipated, while if the banket were a lode of infiltration it would necessarily decrease in richness as great depth was attained. If the mining engineers and geologists of the Rand had been frank even at that time they might have spoiled the professor's argument, but they did not care to commit themselves to a statement unpalatable to their employers. In the same way the discussion as to whether the distribution of the gold was in 'patches' or 'shoots' was a mere 'sparring for wind' hiding the disinclination to acknowledge that the gold was distributed in a manner involving uncertainty as to the future of individual mines. The denials that 'ore-shoots' in the ordinary sense are discernible on the Rand are now no longer of any consequence, for ample proof to the contrary exists. Indeed, much of the writing and talking on this subject has to be discounted, from a technical point of view, by the fact, as I have discovered, that the ante-

¹As mentioned in the article to which Mr. Horwood refers and which I translated for the *Engineering and Mining Journal*, while editor.

²*Trans. Inst. Min. Met.*, Vol. XVII, p. 53.

chambers of the financial houses are ill adapted for the scientific treatment of such a subject as the distribution of gold in lodes. Even Mr. Horwood, with so much more information at hand, treats the subject in a very delicate way: indeed, he drags a palpable herring across the trail by quoting the statistics of gold production, which, of course, in themselves, afford one of the least trustworthy pieces of evidence on the matter. He mentions the Jupiter, the deepest mine on the Rand (5040 ft. vertical) as being "worked at a profit." The Jupiter has now been shut-down for sundry reasons, of which the only one that counts is the relative poverty of the ore. For the same reason, the Cinderella Consolidated (4627 ft. deep) is also idle. However, it is fair to recall the fact that Mr. Horwood controverted Gregory's argument in regard to persistence of richness being allied to an alluvial theory, by quoting De Launay's suggestion that if the blanket were a placer deposit then a diminution in richness would be inevitable as distance from the former shore-line was reached. Mr. Horwood argues that if the blanket be a 'lode formation,' then far greater persistence of ore can be expected; he adduces the fact that the depth of the deepest existing workings is less than one-fiftieth of the length of the lode as measured along its strike, and that owing to the walls being kept apart by the intervening pebble-beds, the extent of profitable ore on the dip is likely to be equal to that ascertained along the strike. This, of course, is a geological inference running counter to established facts. Even on theoretical grounds it is not convincing, for the downward continuity of ore is not determined by structural conditions only. Increase of heat and of pressure are hindrances to that precipitation of metals on which ore deposition depends. The further remarks anent the Rand "developing, more and more, into an enormous, well managed, low-grade goldfield" are not at all to the point. Geologically the persistence of the blanket is an interesting fact; economically the obvious impoverishment of it is a depressing factor. In this part of his treatise, Mr. Horwood speaks with the voice of the geologist, saying smooth things in the house of finance, although his hands are those of an engineer. This is, to criticize frankly, the one weak spot in his treatment of the subject, but I emphasize it more in a spirit of good humor than to detract from the great value of his research.

As regards the placer origin of the blanket, it is interesting to turn to an undoubted fossil placer, in order to see in what respects any resemblance exists. Among several buried deposits of gold-bearing alluvium, I shall refer to the beaches of Nome, which I examined in 1908.

Three such deposits have been traced, besides intermediate patches of minor extent. The First Beach is on the present shore-line; it was discovered in 1899, and has yielded \$2,000,000 in gold. This deposit is still being re-formed by tidal action, but as first discovered it represented the cumulative effect of a continued concentration of gold, garnet, and magnetite in the form of a fringe of heavy sediment at the tidal limit of Ber-

ing Sea. The garnetiferous sand containing the gold is 6 in. to 2 ft. thick, and from 3 to 5 ft. wide, dipping seaward at an angle of 5°. It has been formed by the erosive action of the waves upon the edge of the coastal plain, which terminates in an escarpment 10 to 20 ft. high. The coastal plain is an alluvial delta having a sea-front of 30 miles and a central width, to the foothills, of 4 miles. It represents the detritus brought from the hinterland by a number of streams that deposited the products of erosion upon a bottom that formerly was subsiding but now is undergoing slow elevation.

After the present beach had been successfully exploited, the others were found, partly by accident, partly by aid of geological inference. These other deposits are raised beaches, the Second being 37 ft. above mean tide, and the Third 31 ft. higher or 68 ft. above sea-level. Both of them extend in a sweeping curve so as to form a flat arc of which the present sea-shore is the chord. The Second is half a mile inland, while the Third is 3 miles, as measured northward from the beach at Nome. Both were indicated by mounds of terraces representing the line of former escarpments. The Second is capped by pebbles and gravel containing water-worn fragments of sea-shells. The gold lies on bedrock, which is schist. Fully \$2,500,000 has been won from this marine placer.

The Third Beach is much the richest, having yielded \$15,000,000 in 7 years. It does not always lie on bedrock. The section (Fig. 1) that I sketched in the Happy New

FIG. 1. SECTION OF THIRD BEACH NEAR NO. 2 SHAFT OF THE HAPPY NEW YEAR MINE.

- A—B Two to three feet of gray quicksand.
- B—C Iron-stained pebbles.
- C—D Gray micaceous sand.
- D—E Sand, with pebbles of white quartz.
- E—F The ruby sand, containing gold.
- F—G Boulders of schist and limestone.
- G—H Two feet of fine gray quicksand.
- Below H Schist bedrock.

Year mine showed about 2 ft. of gray quicksand lying upon the schist, then 3 to 4 ft. of boulders with small gravel, underlying the 8 or 10 in. of 'ruby sand' containing the gold, which was readily visible when I examined a handful of this natural concentrate. Above the deposit came sand with pebbles of white quartz, gray micaceous sand, and iron-stained pebbles, making

7 or 8 ft. altogether, these being capped by the roots of the moss that once covered this alluvial deposit, and above that came the coarse gravel of the present coastal plain, all of it frozen solid from surface to bedrock. The gold-bearing layer elsewhere lies on a false bottom of clay or on the bedrock itself. It has an irregular width: 25 ft. in the richest parts, but reaching to 75 to 80 ft. for considerable lengths. For instance, in the May Fraction \$330,000 was taken from a length of 110 ft., 25 ft. at its maximum width, tapering to 5 ft., and 3 ft. deep. The depth or thickness of the gold-bearing layer is usually 3 ft. The productive portions of the deposit yielded gold at the rate of 15 dwt. per cubic yard. The gold is found to have imbedded itself amid the cavities and folia of the soft schist, so that an inch or two of bedrock is always removed with the overlying sediment.

Space will not permit me to go into further details. Such as I have given suffice to show a great unlikeness to the features of the Main Reef series. The concentration of the gold to a narrow band, at most 100 ft. wide, corresponding to 100 ft. on the dip of the blanket, may be imputed simply to the scale of the precedent geological activities, but it appears to me to be more properly assigned to the essential limitations of such a process of mechanical concentration along the sea-front.

Another ore deposit that provokes analogy is the copper-bearing conglomerate of the Lake Superior region. One of the most persistent orebodies ever uncovered by the miner is the copper blanket of the Calumet & Hecla mine, with its deep level, the Tamarack. This blanket is not the only one exploited for copper; indeed the united thickness of the conglomerate beds in this district exceeds 5000 feet. The pebbles are mainly water-worn fragments of quartz-porphry and allied rocks, cemented by calcite, quartz, epidote, chlorite, prehnite, and copper itself. While copper has been won on a large scale from layers of conglomerate in the Calumet, Hecla, Tamarack, Franklin, and Allouez mines, at least one bed of sandstone was rich enough in copper to be exploited, in the Nonesuch mine. However, the more numerous mine workings of the region are in beds of cupriferous amygdaloid, such as have given fame to the Quincy, Atlantic, Baltie, and Wolverine mines. Among the minerals associated with the copper in the matrix of the conglomerate are at least three that are prominent in the blanket of the Rand, namely, quartz, calcite, and chlorite. No effort has been made by any American geologist to establish an alluvial origin for the copper. On the contrary, it was early recognized, by Pumpelly, that an intimate relation existed between the distribution of the copper and the peroxidation of the ferrous oxide in the encasing rock, indicating the precipitation of copper from solution by ferrous oxide, a reaction familiar in the wet metallurgy of copper. As to the source of the solutions, there is less agreement, but it is a recognized fact that the basic lavas of the region generally contain native copper, some of them being rich enough locally to invite mining operations.

Besides the copper in the beds of conglomerate, and in the amygdaloidal rocks, there exist veins formed along lines of fracture. Some of these have proved extremely productive and contained masses of native copper, the largest weighing no less than 420 tons.³

The Calumet & Hecla conglomerate is from 10 to 25 ft. thick, and dips from 36° to 39° northwest, the profitable portion having the form of an ore-shoot that pitches north. It resembles closely the Allouez conglomerate, exploited in the Franklin Junior mine, where I sketched it as shown in Fig. 2.

FIG. 2. COPPER BANKET IN THE FRANKLIN JUNIOR MINE, MICHIGAN.

The conglomerate has a chocolate tinge owing to the reddish-brown feldspars of the porphyrite pebbles. These range in size from a pigeon's egg to that of a turkey. No copper is found in the foot-wall sandstone, but in the deeper workings of the mine, where the sandstone has thinned to disappearance, the copper is found extending into the amygdaloidal diabase underneath the conglomerate. It is significant that a copper blanket has been formed by infiltration of solutions from which the metal in its native state has been generously deposited, in accordance with reactions suggested by the minerals present. G. Fernekes and H. N. Stokes have made confirmatory experiments.⁴ It is not necessary to accentuate the suggestiveness of these copper-banket deposits in their analogy to the lodes of the Rand.

T. A. RICKARD.

London, March 9

The Editor:

Sir: In the part of C. B. Horwood's paper on 'The Rand Banket' appearing in the *Mining and Scientific Press*, November 1, the author proceeds at some length, on page 676, to show that volume changes in the replacement of quartz by pyrite in the formation of the so-called pyrite 'pebbles', did not take place according to the general statement by C. R. Van Hise,⁵ name-

³'The Copper Mines of Lake Superior.' By T. A. Rickard, 1905. Page 103.

⁴*Economic Geology*, Vol. II, pp. 580-584, and Vol. I, p. 648.

⁵'A Treatise on Metamorphism,' U. S. Geol. Surv., Mon. 47 (1904), p. 209.

ly. that "the volume of the original compound is to the volume of the compound produced directly as their molecular weights and indirectly as their specific gravities."

However, in attempting to prove his contention, the correctness of which is not called into question, he wrongly interprets the meaning of the above quotation. This is indicated when he says "the latter part of this statement means that the weight of the compound produced is the same as that of the material that has undergone dissolution," and when further on he considers somewhat in detail, the results to be expected by using each part of the statement as a separate and distinct proposition. The values for the pyrite volumes which he thus obtains are obviously too great in one instance and too small in the other.

The two factors, molecular weight and specific gravity, cannot be considered independently. By definition $r = m/g$ where

v = molecular volume,

m = molecular weight,

and g = specific gravity.

The following operations are evident:

$$1) \quad vg/m = 1$$

$$2) \quad vg/m = r'g'/m'$$

$$3) \quad v/v' = gm'/mg.$$

These equations hold true in comparing any two solid substances. Substituting the proper values for quartz and pyrite, we have that

$$\frac{\text{the vol. of the pyrite}}{\text{the vol. of the quartz}} = \frac{2.7 \times 120}{60.4 \times 5} = 1.07$$

If, therefore, the replacing pyrite were deposited 'molecule for molecule' its volume would be but 7% greater than the volume of the original quartz.

Having concluded that the principle stated by Van Hise is incorrect, Mr. Horwood says "possibly the molecular volumes of the two substances * * * affect the question. The molecular volumes of quartz and pyrite are 22.8 and 24; there is so slight a difference between them that, judging from the particular occurrences under consideration, it might easily be that the volume of the pyrite is to that of the replaced material either inversely, or directly, as their molecular volumes. If so, the evidence indicates that the changes in volumes are inversely as their molecular volumes."

Now, inasmuch as the molecular volumes vary directly as the molecular weights and indirectly as the specific gravities, the author's statement amounts to precisely the same thing as the quotation from Van Hise, and Mr. Horwood is, in reality, indicating that a possible relation exists, which relation he has just attempted to disprove.

A Correction

The Editor:

Sir—I have just noticed in the last number of the

Mining and Scientific Press the account of the presentation function of the Mining and Metallurgical Society medal to Mr. Hoover, in which the sole credit is given to me for the souvenir program. This is entirely wrong, as the credit should be given to James F. Kemp, my part in the work being that of carrying out Mr. Kemp's clever suggestions. Will you please have this matter corrected in your journal, as I do not care to be sailing under false colors.

E. GYBBON SPILSBURY.

New York, March 28.

Agitation at the Nevada Hills

The Editor:

Sir—Mr. Eames has earned our gratitude by his letter in your issue of February 28, in which he comments on the figure of costs which I quoted from Mr. Megraw's valuable article in the *Engineering and Mining Journal* of March 29, 1913. Had Mr. Eames given the detailed figures on which the costs were based when this article first appeared, I would have with pleasure referred to his statement in my 'Annual Review.' As it was, I was anxious to have some such statement as that which Mr. Eames has now given us, as it was difficult to conceive how it could be that the costs of practically the same method at two different mines—I did not refer to the still cheaper agitation cost by a different method at the Goldfield Consolidated or elsewhere—could differ so greatly.

To all of us who have to conduct tests on the treatment of refractory silver ores a scheme of interrupted agitation is apt to commend itself, and we may perhaps have gone so far as to design equipment based on this, but the Nevada Hills figures tended to blight our hopes, the more so as immediately prior to the statement of operating costs was the statement of chemical consumption in detail with no reference to the fact that the costs for this were included under Settling and Agitating. But we are glad to have Mr. Eames' figures, even though the cost of \$0.167 for power and labor for 48 hours agitation seems heavy when contrasted with, say, the costs of prolonged agitation at the Hacienda, San Francisco, or San Rafael installations.

In pioneering new practice one may not at the outset attain the results readily accomplished when greater experience has been gained, and it is just such new practice as has been carried out by the Nevada Hills company which we anxiously watch in the hope that it may prove a step toward the solution of our difficulties in the treatment of certain ores. But Mr. Eames is silent as to my point that even in spite of the interrupted agitation and the heavy cost of this, the cost for filtration is still abnormal; it has been suggested that interrupted agitation combined with the counter current decantation of the rich solutions should result in rendering possible, if not the entire displacement of filtration, the relegation of this to a secondary place.

ALFRED JAMES.

London, March 18, 1914.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Carbon costs, in diamond-drilling at the Goldfield Consolidated mine last year, were 71 cents per foot drilled.

Sinking the new 18-ft. diameter circular shaft of the Crown Mines, Ltd., on the Rand, covered 187 ft. in January, against 217 ft. in November. It is now 1202 ft. deep.

Bodlanger suggests that the following reactions take place when gold is dissolved in cyanide solution:

Ore broken in the Mt. Morgan mine, Queensland, amounted to 2.5 tons per 8-hour shift during the past half-year. The ore handled per underground employee was 1.32 tons. Miners on contract averaged \$4.17, and shovelers \$3.28 per shift.

Coal resources of Queensland, Australia, are estimated by the government geologist, Benjamin Dunstan, as 409,700,000 tons actual, and 2,201,300,000 tons probable reserves, in the total area of 670,500 sq. mi. Seams not less than 12 in. thick, down to 1000 ft. are included.

The new tube-mill plant at the Knight's mill, on the Rand, consists of five 16.5 ft. by 6 ft. diameter mills fitted with Schmidt feeders and Osborne liners, and driven by motors. The drive end is the discharge end. In December, according to *The South African Mining Journal*, four mills and 220 stamps crushed 38,830 tons of ore, equal to 6.6 tons per stamp day. The full equipment has a capacity of 45,000 tons per month. In September last, before the tube-mills were installed, the residue contained 0.487 dwt. per ton, but this has now been reduced to 0.262 dwt. per ton, at a cost of 12 cents per ton.

Testing cyanide solutions at the Lake View mill, Kalgoorlie, is done as follows, according to J. P. Caddy:

Cyanide: Take 20 c.c. of solution, add 2 to 4 drops of neutral 10% KI solution and titrate with AgNO_3 solution (1 c.c. = 0.01% KCN) to yellow color.

Protective Alkali: Take 20 c.c. of solution, add double the amount of AgNO_3 solution required for the cyanide test, and titrate with N/100 KOH or HCl with phenolphthalein indicator. By this test the solution appears slightly acid, requiring about 1 c.c. N/100 KOH to neutralize. (The addition of excess $\text{K}_2\text{Fe}(\text{CN})_6$ before adding AgNO_3 makes a slight difference to the titration, but no protective alkali is indicated.)

As an indication of the amount of magnesium salts in solution, a daily test is made by adding 100 c.c. of saturated lime water to 100 c.c. of the cyanide solu-

tion, and estimating the CaO remaining in solution after the precipitation of the magnesium salts, by titration with acid. The CaO required to precipitate the magnesium salts is about 0.8 lb. per ton of solution.

Gold is used only in a very limited degree to color glass. It may be used according to circumstances to impart either a ruby, carmine, or pink color. It is used in the form of oxide and purple of cassius (a mixture of tin and gold) and sometimes in the form of gold leaf. The metal is added while the glass is in the molten state and on the first cooling the glass is still colorless, and it is only when re-heated that the light red color appears, and it increases in intensity until it finally will turn black. This colored glass can again be rendered colorless by fusion and slow cooling; its color is again produced by a repetition of the heating process. If however, it is suddenly cooled, it cannot again be made to resume its ruby color. This should prove that no chemical change takes place, and that all the phenomena are due to molecular structure alteration. The Bohemian ruby glass is made by melting fulminating gold with oil of turpentine and other ingredients and it has been estimated that about one-twentieth of a grain of gold is combined with about 150 parts of glass ingredients. Copper is more generally employed to color glass red, and the use of this metal for this purpose dates far back into antiquity and all through the Middle Ages it was employed to produce the reds which we see in the fine old windows left by our ancestors for our admiration.

Compounds in cyanide solutions have interfered with the assay of the latter by the lead acetate method, according to G. Simpson, of the Ketahoen mine, Sumatra. J. C. Clennell, when asked to explain this, said that in the case of a solution from Central America, containing copper, ferrocyanide, and molybdenum as the chief impurities, a finely divided blackish brown turbidity occurred on adding zinc dust and lead acetate, and acidulating. This would not settle in a dense form and was extremely tedious to filter, though the precipitation of gold and silver was apparently complete, as re-treatment of the filtrate with fresh zinc dust, etc., gave practically no further amount of precious metal. In using this method, Mr. Clennell never relies on the collection of the lead precipitate by pressing with a glass rod as described in text-books, but always filters off all the insoluble matter, allowing to drain, and scori-fying before cupelling. It would be interesting to know who was the originator of this process. It was described to Mr. Clennell in its essential points by H. T. Durant in 1900, long before it became generally known as the 'Chiddey method.' The brown precipitate referred to might be any of the numerous substances precipitable by zinc dust in acid solution under the conditions of the test. If the Ketahoen ore is anything similar to that of Redjang Lebong, also in Sumatra, with which he is familiar, selenium, copper, and perhaps manganese might be looked for.

Special Correspondence

JOHANNESBURG, TRANSVAAL

GOLD PRODUCTION IN JANUARY.—RELATIVE PROPORTIONS OF THE VARIOUS DISTRICTS AND OTHER PROVINCES.—DIAMOND PRODUCTION IN 1913.

Statistics issued by the mines department for January show that, despite the strike, the total value of the mineral output of the Union of South Africa showed an increase of £19,745 over that of December. The total value, excluding diamonds, was £3,136,256, made up as follows: gold £2,774,721; base minerals, £178,417; coal, £174,971; and silver, £8147. It will be noticed how largely gold enters into the value of the mineral production of South Africa, the bulk of which comes from the Witwatersrand fields, as the following figures will show:

| District. | Mines. | Stamps. | Tube-mills. | Output, oz. |
|---------------------|--------|---------|-------------|-------------|
| Witwatersrand | 52 | 9030 | 277 | 622,095 |
| Heidelberg | 3 | 105 | 2 | 7,337 |
| Klerksdorp | 3 | 69 | 2 | 3,257 |
| Total | 58 | 9204 | 281 | 632,689 |

The Heidelberg and Klerksdorp fields, although mentioned separately, are part of the Witwatersrand gold basin, and really ought to be treated as part of the Rand. The insignificance of the other Transvaal goldfields outside of the Rand is shown in the following statement:

| District. | Mines. | Stamps. | Tube-mills. | Output, oz. |
|----------------------|--------|---------|-------------|-------------|
| Barberton | 12 | 202 | 3 | 6,795 |
| Pilgrim's Rest | 14 | 151 | 4 | 13,557 |
| Pietersburg | 2 | 10 | — | 174 |
| Total | 28 | 363 | 7 | 20,526 |

Seeing how much the gold production of South Africa is dependent on the Rand, no surprise need be expressed at the unsettled feeling the Chamber of Mines' report, with regard to the life of the Rand and submitted to the Government Economic Commission, has produced both here and in Europe. Some attempts, it is true, have been made in several quarters to minimize the value of this evidence, but in its broad aspect the attempt to gauge the life of the Rand is probably as correct as it is possible to make it, always bearing in mind that the estimate is based on today's conditions, which may or may not change considerably in the immediate future. How unimportant is the gold production of the Transvaal outside the Rand is shown by the fact that it does not represent more than what several single Rand companies are producing. The value of the Cape and Natal provinces as gold producers is shown by the fact that, while the latter did not produce any gold in January, the former only produced 2 oz., which adds still more to the importance of the Witwatersrand goldfields when compared with the few others in the Union of South Africa. Another interesting feature of the figures issued by the Mines Department of South Africa for January is the inclusion of the figures relating to the 1913 production of diamonds in the Union. The total production of diamonds produced last year throughout South Africa is given as 5,163,546 carats by weight, valued at £11,389,897, as compared with 5,071,882 carats, valued at £10,061,489 in 1912, an increase of 91,664 carats, valued at £1,328,318 for last year, due entirely to the better demand and higher prices paid for diamonds in 1913. There were no new diamond discoveries of note during the year, although every effort was made in that direction. The

Cape province, including the Kimberley, is above the other provinces as a diamond producer, the total output being 2,461,892 carats, valued at £6,995,438, which practically all came from Kimberley. Next comes the Transvaal with 2,156,897 carats, valued at £2,726,663, nearly all of which again came from the Premier mine near Pretoria. The Orange Free State only produced 544,756 carats, valued at £1,667,706.

BUTTE, MONTANA

'SAFETY FIRST' MOVEMENT AT BUTTE.—THE CITY OF BUTTE.—NEW LEACHING PLANT AT HELENA NEARLY COMPLETED.

The Anaconda Copper Mining Co. has organized a 'Safety First' department with a view to systematizing its efforts for the protection of its employees. The organization of this department has been placed in charge of Charles W. Goodale, who is now visiting various Eastern mines and works with a view to getting ideas for the campaign in Montana. A circular for the guidance of miners, and another with instructions to mine bosses, has been issued. It is thought that many accidents can be averted by carefully instructing employees, and by laying down more definite rules.

Butte refuses to act as a mining camp. In place of the temporary structures which usually satisfy the needs of mining towns, Butte demands, and gets, permanent buildings of both a public and private nature. The railroads are usually slow to build costly depots for mining camps, but not so in Butte. The Northern Pacific and the Oregon Short Line have had for some time a large expensive depot at Butte.

PART OF BUTTE.

The Great Northern railway has just completed a commodious and artistic depot which would be a credit to any city. Now the Milwaukee is preparing to spend \$250,000 in the erection of another depot for Butte. If the confidence of the railroads counts for anything, the future of Butte seems pretty well assured.

The stockholders and others interested in the Northwestern Metals Co. are now to find out whether their dreams will come true. The reduction plant of 1000 tons daily capacity, erected near Helena, Montana, is nearly ready to start. There has been a lot of adverse criticism of this enterprise, whether justified or not I am not prepared to say. Criticism of new metallurgical methods, in these days of rapid advance, is dangerous for any but the most skilled and experienced chemists. The process is one of leaching and is devised to treat complex sulphide ores. The bases of the ores are all chloridized with chlorine gas, and are then precipitated in groups. The iron and manganese are precipitated first by zinc carbonate and sodium hyperchlorite. Then the lead, copper, silver, and gold are precipitated by zinc shaving. Finally the zinc is precipitated by sodium carbonate. The chemicals are practically all made at the plant. The Butte & Pensacola company has acquired six claims adjoining its property in the Carbonite district. The claims now total 500 acres, all of which can be developed by one main adit.

WASHINGTON, D. C.

MINING LEGISLATION BEFORE CONGRESS.—BILL FOR LEASING CERTAIN MINERAL LANDS.—ACTION BY CALIFORNIA MINING MEN.
—REVISION OF THE GENERAL MINING LAW.—THE RADIUM BILL.

In spite of the fact that the action of Congress on the Panama canal tolls question has put everything else in the background, last week was one of busy progress in the proposed legislation concerning the mining industry. Most attention has been attracted by the public hearings before the House Committee on Public Lands in connection with the bill providing a general leasing law for petroleum, gas, phosphate deposits, and coal lands, which was introduced by Scott Ferris, representative from Oklahoma, who is chairman of the committee. The bill has the strong backing of the Department of the Interior, and is pretty sure to pass, though it will probably first be amended somewhat. A good deal of the time of the committee was taken up by the attorneys for California miners, whose efforts to oppose the bill reminded the hearers of the story of the jury that acquitted the accused out of sympathy for him because he had such a poor lawyer. One of the attorneys could not tell how many companies he represented, what their names were, or how many acres of land they held, and when the statement was elicited that companies holding thousands of acres had not attempted to secure patents for more than one claim at most, the situation looked dubious for the oil operators. Later, Clay Talman, commissioner of the General Land Office, was put on the stand and testified that over 300 applications for patents have been pending in his office, some of them since 1910, without being cleared up, and that if more applications had been filed, even less progress would have been made, and the Californians began to cheer up. The testimony of George Otis Smith, director of the U. S. Geological Survey, also helped the California independent operators more than they seemed to be able to help themselves. It is fairly clear that some parts of the original bill will need to be amended. One of the difficulties is what to do with the operators who are on withdrawn lands. While prior rights are bound in the end to be protected, it would simplify matters if some compromise could be effected and avoid litigation. An agreement has about been reached to the effect that such locators shall have preference rights to lease the grounds they occupy and that pending final decision they be permitted to sell oil, a reasonable portion of the returns being impounded to secure the royalties in case any prove collectible.

The limits outside which the prospecting for the discovery of new fields is to be stimulated, by the grant of a larger area, also calls for much discussion, since it depends upon the geological structure, and in some areas wells a few miles away would be as clearly in a new field as though they were 50 miles distant. It is urged that the zones that are 50 miles from any producing well are comparatively few, and of exceedingly dubious value to the prospector; but on the other hand, it is pointed out that the present situation in California does not call for increased production and there is no great desirability for stimulating new discoveries except in remote districts. The question as to what disposition is to be made of the improvements which a locator has made, in case the land is leased to some one else, is also a burning one. It has been suggested that he should be given a patent to part of the ground and required to lease the rest; but as the result of this would be that he would put all his wells and pumps on the patented ground, such an arrangement would not cover the case. Another suggestion is that he be compensated for his improvements, and a third that the Navy Department take these lands for its naval reserve, paying him for his improvements. Some of the more important Californians are quite reconciled to the idea of a leasing

law, since the present arrangement is entirely unworkable. Strong opposition to the leasing of coal lands is manifested by E. T. Taylor, representative from Colorado, who insists that it makes the cost of coal greater to the consumer and retards the development of the western states. When one reflects that coal sells at many mines for about \$1 per ton at the pit mouth, and for several times that to the consumer, a small royalty does not seem so serious a matter to the general public as does the question of freight rates and selling costs. The hearings on this bill will be resumed toward the end of next week.

Some time ago a bill was introduced into the Senate providing for the appointment of a commission of three to consider the general mining law, and draw up a proposed new code for submission to Congress. Unfortunately, the bill provided that these three men should all be mining lawyers. Representatives of the American Institute of Mining Engineers and the American Mining Congress presented their ideas on the subject before the House Committee on Mines and Mining, and E. T. Taylor has introduced, at their instance and with the approval of the Bureau heads concerned, House bill 15288, which provides for a commission of five who shall be chosen for their experience in or knowledge of mining and mining law, and who shall serve without compensation. The provision that the commissioners shall receive no compensation ensures that only high-grade mining men who would look upon the duty as a public service will wish to serve upon the commission. The bill appropriates \$25,000 for the expenses of the commission and the salary of its secretary, and requires that hearings shall be held in Alaska and the western states, and a report made within one year after the passage of the act.

The hearings on the radium bill have been concluded, and in all probability the bill will eventually pass essentially in its present form, as ample opportunity has been afforded to file locations in all the likely ground in Colorado. The bill introduced last December providing for the establishment of 10 mining experiment stations has been lying idle ever since, but will probably soon be taken up again.

NEW YORK

FEELING REGARDING COPPER.—BRADEN SHARES.—GOLDFIELD DISTRICT SHARES, AND OTHER STOCKS IN NEW YORK.—ANOTHER LOW-GRADE PROPERTY.—AMMER COSTS.—CALUMET & HECLA SUBSIDIARIES.—MASON VALLEY.—STEWART AFFAIRS.—BINGHAM MINES COMPANY.

The remaining 'bullish' spirit in New York centres around the copper situation. Arguments for and against a betterment in copper prices have been worn somewhat threadbare. As a matter of fact, the general business situation is much more of a controlling factor than any phase of production, consumption, or export demand. The copper producers themselves appear to be more confident of the future than anyone interested, and are predicting higher prices, and a market that is to be more and more in the hands of the producers.

The chief speculative issue for the time being is the Braden Copper Co., in connection with which there are many over-worked market rumors, the latest being that all idea of further financing has been abandoned, that the present mill is to be made to serve by some changes and additions which will give it 35% added capacity. If there was any general market, with enough trend in a given direction to make headway, Braden would undoubtedly be a favorite market counter. As it is, it has been advancing slowly, the shares apparently being picked up by investors.

There has been a little recent effort to revive interest in the Goldfield issues, but what little market traders could make remained so wholly professional in character that quotations meant little. The activity in Goldfields centred around Atlanta. It is said that some months ago a Philadelphia house

bought 100,000 shares of Atlanta from the Company, and that the recent activity was due to a campaign undertaken by the house mentioned for the purpose of distributing this stock. The fact remains that whether one considers copper shares, assured of long life and present or early dividends, or the wholly speculative issues of Goldfield or Tonopah, there is no 'swing or snap' to the market movement, though this is no more true of mining issues than it is of railroad or industrial shares. Except for a very few exceptional mining enterprises, there are no new things going forward in which the public is asked to take a part. Alaska Gold Mines has met with an apparent degree of success, though it is stated now that it will require a considerable length of time to get to the initial dividend, from which cautious statement lower prices should be quite safely predicted. The public likes the promise of early and substantial dividends, better indeed than it does a present dividend of more modest proportions. While it is true that there are few new mining organizations in which the public is asked to share, there is some work being quietly prosecuted. John G. Worth, representing a syndicate of New York people, is examining a property at El Rito, New Mexico, said to be one of the largest low-grade gold deposits ever exploited. The present work is confined to experimental treatment of the ore, on the solution of which is said to depend wholly the measure of success to be attained. The New York people interested are financially strong, and if it is eventually proved that the ore can be profitably treated, Alaska Gold will have a rival. It is said, in the way of immense tonnages and large profits from very low-grade ores.

A forcible illustration of the cost of the strike in the Michigan copper country is shown by the recent report of the Alameek company. Comparison is made in copper costs between the first half of the year when the cost was 10.01c per pound and the latter half of the year when it rose to 22.5c per pound. Net earnings for the year were \$207,119 as against \$1,465,000 in 1912. Alameek paid dividends of \$11 per share in 1912, but was obliged to cut into its surplus to the extent of \$612,000 to do so. The property is one of the most promising of the newer mines of the Lake Superior region and it will be recalled that this interest is one which made such a bitter fight against the proposed Calumet & Hecla merger about two years or so ago, and which consolidation was abandoned, largely on account of the unwillingness of the Alameek to be included with older properties nearing the point of exhaustion. The Lake Copper mine, which had such a sensational career, being at one time hailed as the long-sought successor to the original Calumet & Hecla, has been wholly shut down since the labor troubles became acute. Regarding the Calumet & Hecla Mining Co., it is somewhat surprising to learn that the present Company's control over its subsidiaries permits a considerable degree of independent action. For instance, in the sales of copper each subsidiary acts for itself independently. Naturally, it would be supposed that concentrating the selling of the entire output of metal in one agency would be a great advantage, and result in better prices. Evidently experience does not justify this conclusion.

The fourth annual report of the Mason Valley Mine Co. has just been mailed to shareholders. It covers operation for the year ended December 31, 1913, and shows a production of 1,166 tons of copper matte, containing 11,691 5/16 lb. copper, 792 1/2 oz. gold, and 121,835 oz. silver. The report covers the second year of the operation of the Company's plant, the quantity smelted during the year being 227,855 tons, of which approximately half was from the Company's mine and half custom ore. The smelter has proved satisfactory and is now converting its own matte.

The market position of Stewart stock is being carefully watched by some Western interests, which have been inclined to take a 'short' position on the theory that the stock basing for more than the net value of its known ore reserve.

holder of United Copper collateral, including a large block of Stewart, having had a share in the large loan made to the United some two years ago. The disposition of this holding has been the controlling influence in Stewart for some time, but apparently it has not been possible to get up sufficient public interest at any time to permit of distribution.

The Bingham Mines Co., which controls the old Eagle & Blue Bell at Tintic, Utah, is making some good financial progress. On the first of the month the Company paid off \$250,000 first mortgage bonds of the old Bingham Consolidated Mining & Smelting Co. This completes the retirement of the original issue of \$902,000, in addition to which there have also been retired \$577,789 second-mortgage convertible bonds, the latter issue having been refunded by the issue of \$600,000 first mortgage convertible bonds. Bingham Mines receives 20c. per share annually upon 694,999 shares of Eagle & Blue Bell, which it holds.

MELBOURNE, AUSTRALIA

AUSTRALIAN GOLD YIELD. GENERAL DECLINE.—WASTE OF TIMBER RESOURCES.—VICTORIA DREDGING.—BOARD'S ADVERSE REPORT.—QUEENSLAND COAL AREAS.—BROKEN HILL. SOME INTERESTING FIGURES.

The gold yields of the various states are gradually being published, though in most cases the figures are only approximations. The New South Wales yield was 149,657 oz., as compared with 165,295 oz. in 1912, a decline of more than 9%. About the same proportional drop is shown in the case of Victoria, the decline amounting to as much as 45,198 oz., to a total of 434,932 oz. Queensland's fall is much heavier, amounting to 83,047 oz., or nearly 24%, the year's output being only 263,343 oz., as compared with 345,390 oz. in 1912. Tasmania's yield is over 35,000 oz., a decline of more than 7% on the previous year's figures, and South Australia's, 5600 oz., a drop of 15%. The only state where output shows an increase is Western Australia, and even there it is only a little over 2%. The decrease in Victoria alone is more than half as much again as the increase in Western Australia, so that the total Australian figures for the year are certain to be on the wrong side. The Dominion of New Zealand, on the other hand, has done better in 1913 than in 1912, exporting 343,627 fine oz., as compared with 316,671 oz. exported in 1912, an increase of over 8 1/2 per cent.

An editorial in the *Australian Mining Standard* makes a strong statement in regard to the waste of good marketable timber that is going on in Australia. According to the writer, in one portion of the state of Queensland, the Atherton scrub, there was, and presumably still is, lying on the ground, going to waste, cedar worth about \$5,000,000. It seems an excessive estimate, yet it is probably no great exaggeration. Timber is cut down or burnt down to clear land for cultivation, although there are large cultivable areas free of timber absolutely untouched. One of the country's largest assets has been absolutely wasted in this way. New South Wales has recognized her folly in this respect and has taken steps to prevent any extension of the evil, and the sooner the other states follow suit the better it will be for them.

The report of the commission appointed by the Victorian Government to inquire into the damage, if any, wrought by dredging operations in the state is an altogether adverse one. If the report be acted on the industry, which is not altogether to be ignored, will be wiped out. The report was published in the *Journal* of March 14, 1914.

The Queensland Government geologist has issued a review of the coal resources of the state. He estimates the area of the geologically surveyed coal measure at 72,000 square miles, of which 20,000 are recognized coalfields, the remainder consisting of lands known to contain coal, but not yet found to be valuable for coal-mining purposes. He draws special attention to the basin of the Dawson and Mackenzie rivers,

which contains far more probable resources than all the other parts of the state put together. Conspicuous among the large number of known seams in this basin is the 20-ft. seam in the Mackenzie River area and the 66-ft. seam in the Clermont area, both coals being of good quality. Other noticeable occurrences are 20 ft. of fine coal in the nine seams of the Burrum area, 20 ft. of coal in the Callide area, and a 60 ft. seam at Waterpark Creek. The table given, which has been built upon an estimation of seams not less than 12 in. thick, and not more than 1000 ft. below the surface, the estimation of quantities below this depth being found to be impracticable at the present time, shows an actual reserve tonnage of 409,700,000 and a probable reserve of 2,201,300,000 tons.

The following interesting facts regarding the great New South Wales field, the Barrier, or Broken Hill, were included in a report presented by E. R. Bowring to the Dominions Trade Commission, which recently visited Australia, and has recently been published. It states: (1) that the Broken Hill field is the largest mining district in Australia; (2) that it produces practically all the zinc, and about 85% of the silver-lead obtained from mines in the Commonwealth of Australia; (3) that the value of the metals produced from the mines up to the end of 1912 was over \$300,000,000; (4)

MOLDING MARKET LEAD, BROKEN HILL PROPRIETARY REFINERY, PORT PIKE, SOUTH AUSTRALIA.

that the dividends and bonuses paid by the various Broken Hill mining companies, with an authorized capital of between \$2,000,000 and \$25,000,000, up to the end of 1912, were over \$75,000,000; (5) that the Port Pirie works are said to be the largest lead-smelting works in the world, and produce an output of lead which has exceeded and now approximates 10% of the world's total supply of that metal; (6) that the Broken Hill mines produce about 20% of the world's production of lead and zinc; (7) that the iron ore deposits at the Iron Knob constitute the most extensive known deposit of any metal ore in Australia, and comprise one of the largest, if not the largest, known iron ore deposits in the world. Mr. Bowring further gave the total output of the smelters at Port Pirie and Broken Hill, up to May 21, 1913, as: lead, 1,354,034 tons; silver, 158,408,072 oz.; gold, 98,303 oz.; antimonial lead, 11,869 tons; spelter, 6584 tons; lead concentrates, 1,261,980 tons; and zinc concentrates, 573,606. With respect to the Iron Knob and its proposed development, Mr. Bowring says: "The extent of the deposits has for some time been known to be considerable, and although the full area of the lode has not been tested, it extends for at least a mile in length, and the reserves have been estimated to comprise as much as 150,000,000 tons. The existence of this immense lode led the Broken Hill Proprietary Co. to decide some time ago on the establishment of steel works at Newcastle, in New South Wales, and to utilize the iron ore at the Iron

Knob for the manufacture of steel. The ore appears to be suitable for the manufacture of high-grade steel, containing a low percentage of phosphorus—namely, from 0.03 to 0.05%, and about 65% of iron."

TORONTO, CANADA

NIPISSING DIVIDEND.—MCKINLEY-DARRAGH IN 1913.—HARGRAVE AND RIGHT OF WAY MINES.—BONUS FOR RADIUM ORES.

As was anticipated, the Nipissing company has reduced its returns to shareholders by abandoning the bonus of $2\frac{1}{2}\%$, which has been paid for some years along with the regular quarterly dividend of 5%. The yearly statement of the McKinley-Darragh-Savage Mining Co. shows a considerable falling off in profits and a decrease in the ore reserves. The output was 2,214,383 oz. as compared with 2,717,383 oz. in 1912. The net profits were \$771,487, a decrease of \$382,361; and the ore reserves have fallen from 5,368,500 oz. to 3,210,000 oz. At the Right of Way, where work has been resumed, a vein on the 120-ft. level, 2 to $2\frac{1}{2}$ in. wide, which has been driven on for 50 ft., is yielding 3000-oz. ore. The annual meeting of the Temiskaming on March 9 resulted in an entire change of the directorate, following a vigorous campaign to oust the old board. The new directors represent the interests controlling the Beaver mine. The Ontario Government has introduced in the provincial legislature a bill providing for a reward of \$25,000 to the first person who discovers radium ores in commercial quantities. The bill also authorizes the Government to reserve all radium in crown lands, and work the deposits, and to purchase private lands containing radium. Similar legislation has been introduced in British Columbia. The action of the Government has been influenced by the proposals before the United States Congress for the acquisition of all radium-bearing ores for the public benefit. Another legislative measure under consideration deals with the fixing of the boundaries of mining claims, giving to the prospector the area actually staked out. Owing to topographical difficulties, it has often been found difficult to describe the claim accurately by measurements, which has frequently resulted in confusion and litigation as to titles. In case of a deliberate intention to include more than the area allowed for a claim, the department is authorized to cut it down to the correct size.

CALGARY, ALBERTA

COAL MINING IN THE PROVINCE: COMPANIES OPERATING, OUTPUT, AND PROSPECTS OF THE INDUSTRY.

The rapid development of coal mining in the province of Alberta is evidenced by the statistics given in the annual report of the Mines Branch of the provincial Public Works Department for 1913. There were in that year 289 companies operating in the province. Thirty-nine of these have a total capitalization of \$107,450,000, without including the Canadian Pacific mines at Lethbridge and Bankhead, the capitalization of which is not given. The total amount of capital invested in the coal-mining industry is estimated at over \$150,000,000. The amount of coal produced during last year was 4,306,346 tons, of which 2,374,401 tons was bituminous, 1,763,225 tons lignite, and 168,720 tons anthracite. Coke was produced to the amount of 65,167 tons, requiring 104,012 tons of coal. The exports of coal from Alberta were about 1,000,000 tons. The output has grown rapidly year by year since the creation of the province. In 1905 it was 811,228 tons, so that the increase during eight years has been approximately 500%. With the growth of population and the opening of the country by railways, affording access to a steadily increasing market, and the introduction of new capital for the opening of additional mines equipped with modern machinery, the industry may be expected to show still greater advances in the near future.

General Mining News

ALASKA

CHISANA

At the Revenue claim, sinking is under way, this being the only shaft on Skookum, except that of Doyle on No. 2 Creek claim, where this work is being done. The latter is down 25 ft. in good gravel, under 18 ft. of muck. Smith and Badden, at the Jumbo, are down 100 ft. in thawed ground, dry and solid, but have found nothing. There is more activity in prospecting now. On the Wilson side everybody seems disappointed. Gold Run is the most favored creek. Prospecting so far has been scattered over a big area of unlikely ground, and only two shafts are down to bedrock, according to L. Lake, of the Revenue claim. E. J. Ives, who is interested in the James claims, has left Cordova for Chisana.

JUNEAU

The report of the Governor of Alaska, J. F. A. Strong, to the Secretary of the Interior, for the fiscal year ended June 30, 1913, has recently been published at Washington, D. C. It covers a great deal of interesting matter dealing with mining, fishing, commerce, and game, etc., in the territory. Several pages are devoted to a complete list of domestic and foreign companies of all kinds operating in the country.

The Sheep Creek tunnel of the Alaska Gastineau company made connection on April 1. The tunnel is 8 by 10 ft. in section and 10,497 ft. long.

KETCHIKAN

(Special Correspondence.)—There is going to be considerable activity in mining here this year on account of the fine results at Juneau, this being a similar belt of country. At Smugglers Cove a number of men are employed, and a large stamp mill is to be erected. The Goldstream, across the bay, has been bonded to an English company. The Gold Standard, at Helm bay, is under bond. King and Elliot have bonded their mines at Helm bay, and at Dolomi several mines will be started in the spring. More men are to be employed at the Valparaiso mine at Dolomi, according to B. A. Eardly, the manager.

Ketchikan, March 20.

NELCHINA

There are about 200 men in this district at present. On 40 creeks about 450 claims have been staked. The ground is wet, and sinking to bedrock is difficult. One hole on Eureka creek showed the ground to be 25 ft. deep. Three drills are going in from Chitina and several boilers from Knik. The Nelchina country is about 3400 ft. above sea-level.

ARIZONA

COCHISE COUNTY

There is considerable activity at Bisbee at present. Seven new McDougall furnaces are to be added to the Copper Queen plant, making a total of 16. Electric hoists are being installed at the Czar and Uncle Sam shafts of the Copper Queen group, while a new head-frame will be erected at the latter shaft. Forms for concrete for the test mill below the Sacramento shaft are being put up. It is said that the Calumet & Arizona company may buy the Wolverine mine.

GILA COUNTY

(Special Correspondence.)—Erection of steel at the Inspiration Consolidated concentrator building was started on March 31, and the total weight for this structure will be about 3000 tons. The American Bridge Co. is now on the last half of its contract. Foundations for the machine tools at the shops are practically complete. There are to be 18 power-driven tools and five large machines in the forge shop. There

will also be woodworking machines installed. To handle heavy gear, etc., there will be gib cranes and a 40-ton overhead traveling crane. An excellent system of transferring machine parts from and to the concentrator and machine-shops has been devised. MacArthur Bros. have nearly finished excavating for the power-plant and cooling basin near the smelter site. The plant will have a capacity of 18,000 kilowatts. Concrete is being poured for the 58-ft. diameter foundation for the 20 by 300-ft. steel stack for the smelter. At the Southwestern Miami, churn-drilling is still under way. Miami, April 2.

Carnotite ore has been opened in fair quantities in the Vanadinite group of claims, three miles north of Globe. They are owned by the C. W. Patterson company. Samples have returned 40% lead, 10 oz. silver, 81 oz. gold, 3.33% of vanadium, and 0.7% uranium.

It is announced that the Cottrell process of electrical precipitation is to be used for fume precipitation at the new smelter of the International Smelting & Refining Co. being built to treat the Inspiration concentrate. While the process will be applied at first only to the fume from the dryers and roasting furnace, rights for the entire plant have been purchased for a lump sum said to be \$45,000. The particular point in the adoption of the process here is to prevent any loss of fine dust which may, in this case contain considerable copper. It is also announced that Wedge furnaces are to be used, and other points are being rapidly decided.

YAVAPAI COUNTY

(Special Correspondence.)—The Ora Bella and Oro Bonita mines, which have been idle for some time, are to be operated again. The two properties are contiguous, and lie in the Bradshaw mountains, a few miles northwest of Cherry Creek district. A long lease has been secured from the owner, Richard S. Barnes, of New York, by Dan A. Bessler and John O'Dell, both practical miners. The two properties were operated a few years ago by the latter, with John Seiss, and gave satisfactory returns. The mines are situated to the west on parallel veins of the Gray Eagle, and have had some work done on them by the Tiger Gold Mining Co. The ore is to be treated at the Company's mill, and work will begin the latter part of April. A new hoist is in operation at the Poorman mine at Walker. Sinking the main shaft is to be resumed as soon as the water is lowered, and from the 200-ft. level a cross-cut will be driven to cut a parallel vein. The Gold Note mine, in the Black Rock district, has been sold by M. H. Ryan to H. W. Flentke and W. H. Temme of Evansville, Indiana. Mr. Ryan has owned and operated the property for some years, and has carried out a practical scheme of development at depth, and the property is well thought of. A large dump has been made, and with the favorable situation of the mine, there being on the ground plenty of timber and water, work can proceed uninterrupted. Black Rock, March 26.

Under the editorship of Aaron H. Powers, the first number of *Yavapai* has made its appearance. It is a monthly magazine devoted to work done in this county, especially at mines. The Verde Tunnel & Smelter railroad, 7 miles long, has been completed and handed over to the United Verde Mining Co. At the Fortune Mining Co.'s property the adit is in 900 ft., and has opened a good shoot about that length.

YUMA COUNTY

(Special Correspondence.)—Henry K. Preston and other Philadelphia people have acquired an interest in a placer property in a basin in the Dome Rock mountains near Quartzite and known as the Middle Camp ground. Extensive tests have been made, and it has been decided to work the gravel by a dry process, using steam-shovels, Quenner disintegrators, and Stebbins dry concentrators.

Philadelphia, Pennsylvania, March 28.

CALIFORNIA

Hugh Wolflin, one of the most experienced mining engineers in the U. S. Bureau of Mines, has been engaged by the State Industrial Accident Commission to assist in its work of safeguarding the life and limb of the mine workers of California. He is at present engaged in a tour of investigation of conditions in the mines of San Bernardino, Kern, San Diego, and Inyo counties for the purpose of conferring with the mine operators regarding ventilation, first-aid to the injured, and safety appliances. Mr. Wolflin's services have been secured with the consent of the federal government, and he will visit every mining district of the state for the above purposes. Proper ventilation and measures to prevent accidents will be thoroughly explained to the employers and employees, and first-aid to the injured, which has never been given much consideration in many of the larger mines of California, will also be dealt with. One of the seven exhibit cars, which the U. S. Bureau of Mines keeps moving about the country to teach 'Safety First' to both employers and workmen, will probably be brought to California and sent into each mining district.

AMADOR COUNTY

The property of the Clinton Consolidated Quartz Mining Co., estimated to be worth \$25,000, and on which no taxes have been paid to the state for 21 years, will be sold by an order of the state controller, John S. Chambers. The amount due to the state is about \$7000. Forty of the eighty stamps at the South Eureka are hung up on account of repairs to the main shaft. An employee at the Kennedy mill fell into No. 18 ore-chute, which delivers ore to a battery feeder, last week, and was suffocated by the ore.

BUTTE COUNTY

W. C. Pershbaker, of Oakland, has started suit for \$50,000 against the P. B. Steifer Mining Co., which owns the Steifer mine near Coutolenc. The Dix or Strauss mine, 23 miles above Chico, has been bonded to G. Henderson and Z. T. Corbett.

ELDORADO COUNTY

Eight men have been sampling the Blue Gauge quartz mine at Ely Park. It is said that the United States Smelting, Refining & Mining Co. had this work done.

INYO COUNTY

Apparatus for the Wilshire Bishop Creek cyanide plant is ready for shipment from Denver, Colorado. On the road near the mine there is 10 ft. of snow at present. A Tetrault 2-stamp mill is to be erected at the Chuckwalla mine by J. B. Evans and associates. The mine has been opened by an adit to 400-ft. depth, and a small vein yields about \$55 per ton in gold, silver, and lead.

LOS ANGELES COUNTY

(Special Correspondence.)—The Western Precipitation Co. has completed arrangements whereby it has obtained complete management of the Slater process for extracting copper ores. A short description of this process was published in this journal of January 24. The reconstruction of the laboratories is under way to accommodate this department of the work, and it is expected to make the equipment sufficiently large to enable all necessary research work to be done at the Los Angeles headquarters. The main work, of course, will be conducted in the field.

Los Angeles, April 1.

NEVADA COUNTY

The report of the North Star Mines Co., operating at Grass Valley, for the year ended December 31, 1913, has just been published, and contains the following data: Mainly from stopes above the 3400, 3700, and 4000-ft. levels, the North Star mine produced 106,090 net tons of ore yielding \$11.312 per ton, or \$1.049 per ton over that of 1912. Development work on and above the lowest level consisted of extending the

5000 and 5300-ft. drifts, and the connection of various levels by raises. What appeared to be the eastern limits of the shoots was reached, and work was stopped. The raises have further developed ore of about average value on and above 5300 ft., and estimated to last for several years. In September, sinking of the main shaft was resumed, and was down 5850 ft. on the incline, equal to about 2200 ft. vertical, at the end of the year. Sinking costs were \$31 per ton. It followed a good-sized but barren vein. A level is to be opened at 5600 ft. Total development covered 3158 ft. against 4601 ft. in 1912, at a cost of 48c. per ton milled. The mill produced a total of \$1,200,096, of which \$938,262 was by amalgamation, \$71,090 from 1629 tons of concentrate, and \$190,744 from the tailing. This is equal to 78.18% by amalgamation and 21.82% by cyanidation. The large tube-mill at the Central cyanide plant, which had been used for grinding concentrate, was in December made into two smaller mills, each being installed in the North Star and Central mills. In future the yield from concentrate will not be shown separately. The residue from the cyanide plants was 28c. per ton.

In April the Company completed payment of \$217,823 on

CHAMPION MILL, GRASS VALLEY.

its purchase of the Champion mines, and did 5901 ft. of development. Work on the bottom levels of the Ural and Merrifield veins was rather disappointing. A raise from the 1000-ft. level of the Ural mine to connect with old workings, opened a promising shoot; and a drift at 1350-ft. in the Merrifield has also disclosed encouraging prospects. The Champion 40-stamp mill treated 26,850 tons of ore yielding \$124,179, but the costs of operating the mine and mill were \$241,338. Added to the payment, the outlay on this property last year was \$487,148, and \$858,101 to date, against an out-purchase of \$154,529. Better results are expected in 1914.

In accordance with the new income tax, a depreciation of the property amounting to \$60,005, or 5% of the yield of \$1,200,096, has been written off for 1913, while depreciation on equipment was at the rate of 7½%. The year's results are as follows:

| | |
|---|-------------|
| North Star production | \$1,200,096 |
| Champion | 124,179 |
| Interest and dividends | 35,757 |
| Balance from 1912 | 907,305 |
| <hr/> | |
| Total revenue | \$2,267,337 |
| Operating the North Star mine and mill..... | \$ 551,998 |
| Improvements, etc. | 13,301 |
| Champion mines account | 486,507 |
| Dividends paid | 300,051 |
| Balance (cash, \$213,149; investments, \$581,975, etc.) | 915,480 |
| <hr/> | |
| Total expenditure | \$2,267,337 |

Costs at the North Star in 1913 were as follows: development, 48c.; mining, \$2.895; milling, 47.6c.; concentrating, 11.5c.; cyaniding, 54.2c.; bullion, 3.1c.; miscellaneous, 25.3c.; New York office, 15.4c.; taxes, 26.7c.; and accident and benefit,

NEVADA

ESMERALDA COUNTY

During February the Jumbo Extension produced 1279 tons of ore yielding \$16,659. The mill in 20 days treated 765 tons at a cost of \$2.01 per ton, and 517 tons was sold to the Western Ore Purchasing Co. Net earnings were \$9080 against \$11,553 in January. Development totaled 309 ft. at a cost of \$5.83 per foot. In March, 14 cars of ore was sold and the gross value of this and the ore milled was \$32,900, and net profits \$24,400. The estimated March production of the Goldfield Consolidated is as follows: Ore mined, 30,351 tons; gross value recovered \$337,000; operating expenses, \$175,000; and net realization, \$162,000. So far, the quartz vein opened at 500 ft. in the Silver Pick has been cross-cut for 90 ft., with no walls showing.

MINERAL COUNTY

On April 2 the new leaching plant of the Wagner Azurite company, at Luning, was started. The mill has a capacity of 200 tons per day, and will treat ore containing 2 to 6% copper and \$20 per ton gold and silver. The plant is the first one in the state to use this process, and cost \$60,000. Michigan capital is interested in the property. Frank Everett is manager. After being shut down for 22 years, the Holmes silver mine is to be reopened, under the management of G. E. Hirefall.

NYE COUNTY

The agreed time for not mining ore in the disputed ground between the West End and Jim Butler mines having expired, the former Company has resumed breaking ore. Suit has been started by the Jim Butler company against the West End company for \$250,000 for alleged wrongful extraction of ore from the former's vein. The Belmont company will pay an extra dividend of 10c. per share or \$150,000 on May 1. The total for 1914 so far is \$900,000. On No. 15 level of the Belmont mine, a pump with 300,000 gal. capacity per day is to be installed. The North Star produced 928 and treated at the MacNamara mill 847 tons of ore averaging \$21.91 per ton with a profit of about \$6000. A heavy earthquake shook Tonopah April 6, but no damage was reported.

WASHOE COUNTY

The Copper Lode Mining Co. has acquired the Copper Queen group of claims four miles from Reno. California people are interested in the deal. There is an orebody 10 ft. wide, and some rich ore was extracted last year by lessees. W. J. Thomson is manager.

A meeting of the Nevada Industrial Safety Association has been called at the University of Nevada, Reno, for April 18, by the Governor, T. L. Oddie. The purpose is to effect a permanent organization. Co-operation of the U. S. Bureau of Mines has been secured and good results are expected.

WHITE PINE COUNTY

Development is being steadily done on the sulphide ores in the Emma Nevada and Watson claims, next to the Liberty pit of the Nevada Consolidated, by the Consolidated Copper Mines Co. Five churn-drills are working two shifts, drilling up to 50 ft. each per day. The holes are from 500 to 700 ft. deep. Native copper ore was recently found in the Ora claim.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—Twenty men are employed by the Alberta Development Co. The vein is from 4 to 5 ft. wide. The property includes 200 acres. At the Socorro, 1200 tons of ore is treated per week. During the first half of March 1¼ tons of gold and silver bullion was sent to the mint, also to the smelters several tons of high-grade concentrate. In the Lincoln the vein is 4 ft. wide. Rich ore is still coming from the Pacific. From the Little Charlie the daily output to custom mills is 20 tons of ore. Both the

east and west breasts of drifts at bottom of winze from adit 'C' of the Oaks mine show good ore. The shaft has been started near the portal of adit 'B.'

Mogollon, March 23.

OREGON

BAKER COUNTY

Rich ore has been developed by a raise in the North Pole mine, near Sumpter. Tests are being made at the Ben Harrison to see whether a cyanide plant would be beneficial to ore treatment. Prospecting is under way at the Helen B., Gold Nugget, and Red Boy mines. The latter's mill is crushing ore for lessees.

UTAH

SALT LAKE COUNTY

Foundations for the new crushing plant at the Lark mill of the Ohio Copper Co. are being prepared. Three 24 by 60-in. rolls have been ordered. On March 27 the mill treated 2860 tons of ore which was softer than usual. Three feet of ore assaying from 40 to 50% lead has been opened at 800

THE MOGOLLON DISTRICT, NEW MEXICO.

ft. in the Yosemite mine of the Bingham Mines Co. The manager, Imer Pett, has miners prospecting at 500, 800, and 1100 feet.

SUMMIT COUNTY

In 28½ days, of two shifts each, in March, the Snake Creek tunnel at Park City was advanced 298 ft. It is fitted with electric light and telephone. The Daly-Judge company did 1100 ft. of development in March, with satisfactory results.

WASHINGTON

SPOKANE COUNTY

Transactions on the Spokane Stock Exchange in March totaled 737,221 shares, worth \$67,820. These covered mining companies in this state, Idaho, and British Columbia.

CANADA

BRITISH COLUMBIA

The Standard Silver-Lead Mining Co., a Spokane concern operating near Silverton, has paid a dividend of 2½c. per share, or \$50,000. This makes the current year's total \$200,000.

ONTARIO

The Keely mine, at South Lorrain, now owned by the Huronian Belt Mining Co., is being unwatered. The balance of the purchase price, about \$200,000, of the Burnside claims at Kirkland Lake, has been paid by the Kirkland Lake Proprietary. At 400 ft. in the McIntyre mine there is 200 ft. of \$23 ore, the width being 6 ft. The cross-cut under Pearl lake has been driven 900 ft. The mill is treating 125 tons of ore per day.

10.4c.; less sundry receipts, 2.4c.; making a total cost of \$5.203 per ton milled. The output since May 1884 is 1,141,284 tons, yielding \$15,245,189, and \$4,087,040 in dividends.

PLACER COUNTY

It is said that an English company has taken an option on the Orofina gravel mine, south of Shingle Springs. Floods in the American river have enriched the gravel bars and miners near Idaho Hill are recovering from \$2 to \$5 per day by rockers and sluicing.

PLUMAS COUNTY

New equipment is being added to the Antlered Crest drift-gravel mine, where a lower adit is being driven to cut the lower portion of the Mooreville channel. Gravel yielding good gold content was recently opened in the Bastillon claim, adjoining the Antlered Crest.

SACRAMENTO COUNTY

The real estate and personal property, including a 9-cu. ft. dredge, of the Union Dredging Co. will be sold at public auction April 28 at 11 a.m. on the premises near Folsom, California.

SHASTA COUNTY

The Balaklala Copper Co. is being sued for \$25,000 damages by E. Laudawick, who alleges he was struck by a projecting rock in the transportation tunnel, when he was employed as a motorman on an electric locomotive.

SIERRA COUNTY

Some ore containing gold and arsenical pyrite has been extracted from the Wyoming mine's long adit, near Alleghany. This property is west of the Sixteen-to-One, and is on the serpentine contact. At the El Dorado, a pocket of rich ore, worth \$10,000, was opened last week. The concentrate, weighing 156 lb., returned \$3200 from the Selby smelter. The Mt. Alta gravel mine, on Oregon creek, continues to be a good gold producer. Gravel worth \$1.75 per ton has been opened in the lower adit. Pike City men are interested in the mine. C. N. Chatfield is manager. The Dreadnaught, owned by Owen T. Owens, near Forest City, is opening in a promising manner.

SINKIYOU COUNTY

(Special Correspondence.)—John B. Farish, of New York, has been unable to arrange for another year's extension upon the extensive copper group of Davis and Howard at Clear Creek, near Happy Camp, and has therefore dropped his option upon this property, although his full time has not quite expired. Davis and Howard have begun patent proceedings upon their extensive group of copper claims near Happy Camp, in this county.

Happy Camp, March 28.

COLORADO

THE SAN JUAN

The Denver & Rio Grande railroad has issued an interesting map of this mining area, which includes Mineral, Hinsdale, La Plata, San Juan, Ouray, Montezuma, Dolores, and San Miguel counties. It also gives the value of the gold, silver, copper, lead, and zinc production from 1880 to 1912, inclusive, as published by the U. S. Geological Survey. The respective totals are as follows: \$37,121,674; \$9,004,680; \$3,722,250; \$53,205,787; \$64,570,309; \$68,581; \$11,880,144; and \$66,369,471. Ore shipments from Ouray during the past three months totaled 7608 tons, of which 1287 tons was from the Camp Bird, 4500 tons from the Wanakah, and 667 tons from the Atlas. Prospects for lessees during the coming season appear to be good.

TELLUR COUNTY (CRIPPLE CREEK)

Rumors are again afloat in Colorado Springs that a consolidation of several mines at Cripple Creek is being made in Paris. The deal will involve the Golden Cycle, El Paso, Vindicator, Granite, and others. The output of the district for March was estimated as follows:

| Plants. | Tons. | Average. | Total val. |
|-----------------------------|--------|----------|-------------|
| Smelters | 3,965 | \$55.00 | \$ 218,075 |
| Golden Cycle | 30,000 | 20.00 | 600,000 |
| Portland | 9,520 | 20.00 | 190,000 |
| Portland | 16,800 | 2.67 | 44,856 |
| Stratton's Independence.... | 10,990 | 2.96 | 32,530 |
| Ajax | 4,000 | 6.80 | 27,200 |
| Wild Horse | 1,300 | 3.40 | 4,420 |
| Jo Dandy | 2,000 | 1.40 | 2,806 |
| Isabella | 750 | 2.00 | 1,500 |
| Total | 79,325 | | \$1,121,381 |

Rich ore, supposed to be the Victor ore-shoot, has been opened by lessees in the Isabella property, at a depth of about 500 ft., and is considered to be an important find. The first part of the Free Coinage aerial tramway is in operation. Suspensions being entertained that high-graders were in the Vindicator mine, all exits were guarded on April 2 for their capture. It is said that about \$100,000 will be spent in enlarging the Colburn-Ajax mill. The Golden Cycle main shaft is now 80 ft. below the 1650-ft. level. It will be continued to 1850 feet.

IDAHO

LEMHI COUNTY

The Gilmore mine has been shipping 20 cars of ore per month during the past two months, but in April this may be increased to 30 cars. A rich pocket was opened last week assaying \$900 per ton.

SHOSHONE COUNTY

The Federal Mining & Smelting Co. reports an income of \$1,096,662 from its lead, silver, and zinc during the last four months of 1913. The cost was \$953,413. There were charges of \$317,237 against the income of \$315,051, leaving a deficit of \$2786.

MISSOURI

JASPER COUNTY

During the week ended April 5, production of the Joplin district was as follows: blende, 8,680,670 lb.; calamine, 677,100 lb.; and lead, 1,311,430 lb.; averaging \$37.09, \$21.37, and \$44.68 per ton respectively. For the past 14 weeks the output totaled: blende, 137,917,510 lb.; calamine, 9,085,120 lb.; and lead, 25,553,160 lb.; having a total value of \$3,369,026.

MICHIGAN

HOUGHTON COUNTY

The report of the Ahmeek Mining Co. for 1913 shows that at No. 1 shaft all openings north and south show ground of average quality, save No. 17 level south, which is poor. The same may be said of No. 2 shaft. Mules are used for tramming on No. 12 and 14 levels. Work is proceeding on the additional four stamps, also six boilers and a 2000-kw. low-pressure steam turbine. 'Rock' crushed was 283,749 tons, as against 652,260 in 1912, yielding 9,220,874 lb. of copper. Of this, 9,044,166 lb. was sold for \$1,394,876. The profit was \$176,919, and dividends \$850,000, thus reducing the previous surplus to \$706,128. The cost per pound was 13.30c. During 1913 the Keweenaw Copper Co. drilled 14 holes, with a total length of 7911 ft., on the Ashbed lode.

MONTANA

SILVERBOW COUNTY

Ore shipped from the Butte-Ballaklava mine's 1400-ft. level to the Washoe smelter has varied recently from 4 to 6.94% copper and 7.2 to 8.8 oz. silver per ton. About two cars per day were shipped in March. The Bullwhacker Copper Co. has ordered a Kelly filter-press of 460 sq. ft. filtering surface, to be used in its electrolytic process. Presses are being installed at the Butte-Duluth leaching plant and the Butte & Superior flotation plant.

Personal

EDMUND JUESSEN is at Tonopah.

P. R. BRADLEY has arrived at Juneau.

C. W. MERRILL is at Los Angeles this week.

T. A. RICKARD will visit New York in May.

THOMAS T. READ was at Cincinnati last week.

W. L. SAUNDERS was in Washington last week.

F. B. WEEKS is at Park, Eldorado county, California.

E. A. JULIAN and S. J. KIDDER are in San Francisco this week.

ROBERT SCOTT has returned from the Sunflower quicksilver mines in Arizona.

RICHARD PHILLIPS, of Oroville, has gone to New York for two or three months.

DONALD F. IRVIN has returned to El Tigre, Sonora, from a trip along the western coast.

COURTENAY DE KALB has completed a mine examination near Nacozari and is returning to Tucson.

W. G. ANDERSON has gone to Northbrook, Ontario, as mine manager for the Ore Chimney Mining Company.

H. W. HARDINGE has returned to New York from a two months' trip through the western mining districts.

J. H. MEANS, who has been in charge of operations at the Mawchi tin and wolfram mines, Burma, is in London.

T. N. STANTON has recently been appointed superintendent of mines for the Cananea Consolidated Copper Co., at Nacozari.

AUGUSTUS D. COX has been appointed superintendent of the Nevada Packard Mines Co. of Rochester, Nevada, of which he took charge April 1.

H. A. J. WILKENS, president of the Mines Management Co., will be in London until the latter part of April, in connection with the work of that Company.

KIRBY THOMAS, of New York, has concluded an extensive sampling of the old Phoenix gold mine in the Cave Creek district, north of Phoenix, Arizona.

E. HOGAN TAYLOR, formerly of Kalgoorlie and recently at Redjang Lebong, Sumatra, has been appointed general manager at the Great Cobar copper mine, New South Wales.

J. N. HOUSER, former manager for the American Zinc, Lead & Smelting Co.'s Joplin property, has been transferred to Mascot, Tennessee, where he is manager for the American Zinc Co. of Tennessee.

The U. S. CIVIL SERVICE COMMISSION, at Washington, D. C., announces competitive examinations on May 11 for the following positions with the U. S. Bureau of Mines: Coal-mining engineer, salary from \$2400 to \$4000; assistant engineer of mine tests, salary from \$1800 to \$2400; and mine statistician, salary from \$1800 to \$2400 per annum. The subjects include education, professional experience, and publications or reports.

Utah members of the AMERICAN INSTITUTE OF MINING ENGINEERS are organizing a local section, headed by R. C. GEMMELL, of the Utah Copper Co. A petition is to be sent to the directors in New York City for a charter. This is also to include members in Nevada, if they join the Utah men, and the headquarters will be at Salt Lake City. ERNEST GAYFORD, of Salt Lake City, was made secretary of the meeting, and the following engineers were present and signed the petition to the executive board of the national body: R. C. GEMMELL, C. H. DOOLITTLE, DUNCAN MACVICHIE, ALBERT FRANCK, ERNEST GAYFORD, B. L. LEWIS, A. C. NEBEKER, WALTER FITCH, B. F. TIBBY, FRANK ANDERSON, STANLEY B. SEARS, E. R. ZALINSKI, A. K. TIERNAN, H. HILL, J. C. DICK, R. C. BRADFORD, W. A. WILSON, J. C. MCCHRISTAL, A. H. BARDWELL, and L. S. AUSTIN. GEORGE F. WADDELL was also present. The formation of this branch will be of great assistance in entertaining the visiting engineers in August, toward which the mining companies of the state have contributed \$10,000.

Society Meetings

Schools and Societies

The CHAMBER OF MINES AND OIL of Los Angeles held a 'Safety First' luncheon during the last quarter, according to *Bulletin* No. 21. The guests were members of the Industrial Accident Commission of California. John R. Brownell, superintendent of safety, addressed members on methods used for the prevention of accidents in manufacturing establishments, and explained the ideas of the commission concerning certain portions of the new Workmen's Compensation Act. Early in March members were invited to hear B. M. Buck, chief chemist of the American Sheet & Tin Plate Co., deliver a lecture on the use of copper in steel as a preventative of corrosion. Both lectures were well attended.

The Metal Markets

LOCAL METAL PRICES

San Francisco, April 9.

| | |
|---|------------|
| Antimony | 9 — 9½c |
| Electrolytic copper | 15½—15¾c |
| Pig lead | 4.05— 5.00 |
| Quicksilver (flask) | \$39.00 |
| Tin | 40½—42 c |
| Spelter | 6½— 6¾c |
| Zinc dust, 100 kg. zinc-lined cases, 7½ to 8c. per pound. | |

EASTERN METAL MARKET

(By wire from New York.)

NEW YORK, April 9.—The market for copper, lead, and zinc is quiet and featureless. The first named metal showed a tendency to rise during the week, but fell back again. In spite of an increased production in March, the Copper Producers' report again shows a decrease in stocks. The Braden output for March was 1,801,000 lb. Business on the Stock Exchange has been extremely dull. Bar silver is 58½c. per ounce. In London silver is 26.94d. per ounce. Lead and spelter show no change.

SILVER

Below are given the average New York quotations in cents per ounce, of fine silver.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average weekly and monthly quotations, in dollars per flask of 75 lb. are given below:

| Week ending | Mch. 26. |

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations average about 5c. per lb. higher. Below are given average monthly New York quotations in cents per pound:

Monthly averages.

| | 1913. | 1914. | | 1913. | 1914. |
|-----------|-------|-------|------------|-------|-------|
| Jan. | 50.45 | 37.85 | July | 40.70 | |
| Feb. | 49.07 | 39.76 | Aug. | 41.75 | |
| Mch. | 46.85 | 38.10 | Sept. | 42.45 | |
| Apr. | 49.00 | | Oct. | 40.61 | |
| May | 49.10 | | Nov. | 39.77 | |
| June | 45.10 | | Dec. | 37.57 | |

The production of Netherlands Indies Government Banca tin during 1913 amounted to 253,538 piculs (34,481,168 lb.), against 183,790 piculs (24,995,140 lb.) in 1912.

According to J. Vosselman & Co., New York, the March tin statistics show the following: monthly supplies from all sources to England, Europe, and the United States, 10,333 tons; monthly deliveries to all points, 10,586 tons; and visible supplies (stocks at points, afloat and landings), 18,190 tons. The respective figures in February were 8766, 7493, and 18,443 tons; and in March 1913, 9932, 11,030, and 12,312 tons. Average prices in London and New York in March and February 1914 and March 1913 were as follows: £173.25, £180.5, and £166.5 per ton; and 38.11, 38.85, and 36.85c. per pound respectively.

Aluminum Ore Production

The production of aluminum ore in 1913, according to final figures of the U. S. Geological Survey, was 210,241 long tons, valued at \$997,698, an increase of 50,376 long tons, or 31.5% and \$228,766 or 29.8%, respectively, over the figures for 1912. The states which produced bauxite were, as usual, Alabama, Arkansas, Georgia, and Tennessee. Arkansas led in 1913, its output exceeding that of the previous year. The average price of bauxite per long ton at the mine for 1913 was \$4.75, which differed by only a few cents from the prices recorded for the three previous years. There was more aluminum consumed in the United States in 1913 than in 1912, but the figures showing this consumption cannot be published at the present time, as the import figures are not yet available.

Australian Gold Production

Following are the January returns, in fine ounces, as officially published:

| State. | 1914. | 1913. |
|-------------------|---------|---------|
| New South Wales | 15,769 | 17,083 |
| New Zealand | 29,640 | 29,404 |
| Queensland | 14,914 | 20,591 |
| Victoria | 23,140 | 25,066 |
| Western Australia | 112,023 | 104,706 |

New Zealand produced gold worth £1,459,499 in 1913, and the average for 57 years is £1,439,623. The mints at Sydney, New South Wales; Melbourne, Victoria; and Perth, Western Australia, received 56,680, 45,372, and 125,542 fine oz. respectively in January.

The United States Smelting, Refining & Mining Co. reports as follows for 1913:

| | 1913. | 1912. |
|-------------------------|-------------|-------------|
| Earnings | \$4,555,122 | \$5,497,965 |
| Profit | 3,585,586 | 4,232,965 |
| Surplus after dividends | 830,121 | 1,418,083 |
| Surplus at end of 1913 | 4,478,843 | 3,648,722 |

Company Reports

MT. BISCHOFF TIN MINING COMPANY

This Tasmanian property is one of the most noted in the world, and has paid to the end of 1913, \$12,307,200 in dividends, \$172,800 of which was paid during the second half of 1913. Ore reserves are estimated at 2,176,000 tons of tin-bearing ore. During the last period, 122,601 tons was stamped and concentrated, yielding 600 tons of tin oxide. The smelting works at Launceston treated 619 tons of Company product and 1567 tons of custom product, yielding 399 and 1093 tons of 99.88% tin, respectively. Costs of mining, aerial ropeway, milling, power, and administration, etc., totaled \$1.15 per ton of ore treated. The revenue for the half-year was \$330,000; net profit, \$111,000; dividend, \$172,800; carried forward, \$432,000; and surplus over liabilities, \$153,000.

NUNDYDROOG COMPANY, LIMITED

This is one of the Indian mining companies, operating at Kolar, in the state of Mysore. The superintendent, Charles H. Richards, reports as follows for 1913: A total of 3564 males and 444 females was employed at the mine, 3770 of whom were natives. An average of 33.39 machine-drills was used underground. Water amounting to 152,840,000 gal. was pumped from the mine. Development to 3200 ft. totaled 12,524 ft., 3396 cubic fathoms of stoping, and 240 cubic fathoms of other work. Ore reserves are 150,650 tons, an increase of 12,210 tons. An average of 76.42 stamps was in operation, crushing 3.25 tons per head per day through wire screening. The tonnage milled was 90,650 tons, yielding 73,046 oz. bullion. The cyanide plant treated 94,665 tons, yielding 7332 oz. bullion. The total recovery was \$17.64 per ton. Costs were \$7.28 per ton. The revenue was \$1,584,000. Dividends last year were \$475,200, and \$9,610,000 to date from an output of 1,526,554 tons yielding \$25,297,000.

HEDLEY GOLD MINING COMPANY

This Company operates a mine and mill in British Columbia, and the report covers the year 1913. A total of 70,796 tons of ore was treated, yielding \$656,541 by concentration and \$145,789 by cyanidation, a total of \$802,330. The recovery was 94%. The tonnage was 341 more than in 1912, worth \$12.03 against \$11.19 per ton. The superintendent, Ganer P. Jones, states that the Dickson incline, 8 by 16 ft. in the clear, is down 700 ft., where drill-holes have cut \$20 ore, but another hole from the bottom of No. 5 incline gave only \$7 per ton. Four drill-holes proved a large shoot of \$8 to \$9 ore northeast of No. 5 incline. In the stopes are 10,000 tons of broken ore. Reserves are estimated at 413,000 tons, averaging \$10 per ton. Since the report was prepared, another hole west of the 600-ft. level has passed through 32 ft. of good ore, checking the holes drilled in 1912. An all-the-year-round water-power plant is being constructed at a cost of \$200,000. Dividends totaled \$360,000, and the undivided profits amount to \$272,096.

SOUTH AFRICAN GOLD TRUST, LIMITED

This is a large holding company, having shares in 57 different mining companies operating in South Africa, West Africa, Rhodesia, Brazil, Yukon, California (including Oroville, Natomas, and Yuba dredging), and Mexico. The holdings are not limited to gold mines, but include tin, oil, electric power, and cyanide production. The Company's ordinary share capital stands at £500,000, and the preference share capital at £500,000. During 1913 the sixteenth drawing of £10,000 debentures for redemption, in terms of the issue, has taken place, leaving £90,000 outstanding. The realized net profits on the year's operations, almost entirely derived from

dividends on investments and interest on loans, after deducting debenture interest and all charges, amounts to £99,129, from which the dividend on the preference shares and French Government taxes has been deducted, leaving £68,397, which, with the amount brought forward from last year, namely, £63,444, makes a total of £131,841, subject, however, to depreciation. The directors regret to have to report that the total depreciation amounts for the year to £286,396. This amount has been provided for by charging £150,000 against the wasting assets account, £30,000 against a credit reserved in previous years for unforeseen contingencies, and the balance of £106,396 against the profit and loss account, leaving the sum of £25,445 to be carried forward. The directors regret, under these circumstances, that they are unable to recommend the distribution of a dividend on the ordinary shares. As was the case last year, the depreciation exceeds the declared profit, and the Consolidated Gold Fields of South Africa, Ltd., is, therefore, not entitled to any percentage on the declared profits, and as the directors undertook to be governed by what applied in this respect to the Consolidated Gold Fields of South Africa, Ltd., neither do they get any benefit by way of commission.

AMERICAN SMELTING & REFINING COMPANY

In view of the very unfortunate condition of affairs in Mexico, by reason of which so large a part of the Company's property is at present unproductive, according to the president, Daniel Guggenheim, the directors feel that the shareholders have reason to congratulate themselves on the fact that the earnings of the common stock for 1913 equal 7.47%. The earnings of the Company from mines and from smelting and refining are \$3,570,532 less than during the previous year. Assets at the end of last year amounted to \$189,843,782, made up as follows: Property account, \$140,906,799; investments, \$1,183,653; net value of stocks of ore, bullion, and factory products on hand and in transit, \$26,481,002; working assets, \$3,587,433; current assets, \$16,601,092; and cash and securities in funds, etc., \$1,083,803. Apart from the capital stock and bonds, the current liabilities include: accounts, drafts, and wages payable, \$6,427,880; deferred payments on mining properties, \$330,000; interest on bonds, \$380,100; dividends payable and unclaimed, \$2,045,897; accrued taxes not due, \$321,674; creditor accounts, \$1,307,788; and profit and loss surplus, \$18,495,943. At the end of 1912 the last item was \$16,759,402. Results of the past two years are as follows:

| Income: | 1913 | 1912. |
|--|---------------------|---------------------|
| Net earnings of smelting and refining plants | \$10,926,254 | \$12,568,835 |
| Net earnings from mines..... | 1,185,153 | 3,113,105 |
| From interest, rents, dividends, etc. | 1,318,525 | 1,077,559 |
| Total gross income | \$13,429,933 | \$16,759,499 |
| Expenditure: | | |
| Administration | \$ 896,639 | \$ 758,176 |
| Taxes, including income tax..... | 210,698 | 123,917 |
| Interest on bonds | 824,961 | 872,926 |
| Depreciation | 1,525,518 | 3,013,543 |
| Other charges | 215,576 | 236,692 |
| Total expenditure | \$ 3,673,392 | \$ 5,679,824 |
| Net income | 9,756,540 | 11,079,675 |
| Surplus at beginning of 1913..... | 16,759,402 | 13,699,726 |
| Gross surplus | \$26,515,942 | \$24,779,402 |
| Dividends: | | |
| On preferred stock | 6,020,000 | 6,020,000 |
| On common stock | 2,000,000 | 2,000,000 |
| Total dividends | \$ 8,020,000 | \$ 8,020,000 |
| Surplus | \$18,495,942 | \$16,759,402 |

Decisions Relating to Mining

PLACER CLAIM—SURVEY FOR PATENT

When a placer entry of part of a regular shaped lot composed of legal subdivisions is described in terms of the public surveys as a legal subdivision and may be readily identified by that description, a special mineral survey thereof will not be required.

Archibald McNabb, 42 Land Decisions, 413. September 13, 1913.

PLACER CLAIMS—RULE OF APPROXIMATION

The rule of approximation permitted in entries under the homestead and other public land laws, permitting an entryman to take and pay for a legal subdivision of surveyed ground although the precise area of said subdivision may be found to vary to a small extent from the standard area because of unavoidable variations in the public survey lines, applies also to placer claims but in dealing with placers the rule should be applied on the basis of ten-acre subdivisions.

Ventura Coast Oil Company, 42 Land Decisions, 453. October 3, 1913.

MILLSITE—PROOF OF NON-MINERAL CHARACTER

A millsite claim may be patented where it adjoins the end of a lode claim, provided it be clearly shown that the lode or vein along which the mining location is laid either terminates before the end abutting upon the millsite claim would otherwise be reached, or that it departs from the side-line of the mining claim, and that the ground embraced in the millsite claim is non-mineral in character. A higher degree of proof may be required where the millsite adjoins the lode claim on the end than where it adjoins it on the side.

Montana-Illinois Copper Mining Co. 42 Land Decisions, 434. September 27, 1913.

TUNNEL SITE—NOT BASIS FOR PATENT

Section 2323 Revised Statutes, confers upon tunnel site claimants merely the preference right as against a subsequent lode claimant, to appropriate in the manner provided by other provisions of the mining laws, any vein or lode, not appearing on the surface, which may be discovered in a tunnel projected under the provisions of said section within 3000 ft. from the portal thereof, provided the work thereon be prosecuted with reasonable diligence; but said section does not authorize the sale or patenting of any ground on the exclusive basis of the tunnel location, whether the tunnel be run for the development of veins or lodes already located or is projected for the discovery of 'blind' veins or lodes.

Letter, 1st Asst. Secretary Jones, 42 Land Decisions, 456. October 9, 1913.

PLACER MINING CLAIM—COMMON IMPROVEMENT

Where a deep quarry has been excavated upon one of a group of placer mining claims held in common for the purpose of developing a deposit of marble existing within the group, and has been projected to within a few feet of another claim of the group, and the topographic conditions are such that the marble within such claim can be more economically removed through the existing excavation than through an independent plant of development, a proportionate share of the cost of such improvement is applicable to such claim in satisfaction of the statutory requirement concerning expenditure as a basis for patent. However, the excavation was not allowed as common improvements for other claims situated from 600 to 1200 ft. distant.

American Onyx & Marble Co., 42 Land Decisions, 417. September 17, 1913.

Recent Patents

1,079,786.—PROCESS OF HARDENING COPPER. James A. McLarty, Toronto, Ontario, Canada.

He proposes coating the copper with a material including a compound containing both hydrogen and carbon, and thereafter heating said copper to a temperature of about 1600° F. and then allowing to remain out of contact with air until cold.

1,080,747.—METAL CONTAINER. Thomas J. Buckley, New Brunswick, N. J.

A device of the character described, comprising a hollow contained proper, a hollow neck, a plug, or stopper extending therefrom and a weak portion connecting the stopper and the neck and disposed at an angle to the longitudinal axis of the stopper.

1,081,164.—SMELTING OR REFINING OF METALS AND THE LIKE IN CRUCIBLES. Henry G. Solomon, London, England.

An induction furnace comprising a transformer the secondary of which is formed by an annular crucible, a casing surrounding the transformer, a movable device adapted to close said casing and a bridge-piece for the transformer connected to and movable with said movable device.

1,079,787.—PROCESS OF TREATING METALS. James A. McLarty, Toronto, Ontario, Canada.

This consists of subjecting metals in a heated state to the action of gases and vapors produced by heating a mixture including a carbohydrate and a fat to a temperature below that necessary to produce material amounts of carbon monoxide, said mixture being out of contact with said metal.

1,080,912.—METHOD OF ELECTRICALLY SMELTING VOLATILE METALS. Woolsey McA. Johnson, Hartford, Conn.

The method of smelting ores yielding a volatile metal which consists in electrically heating a charge proportioned to yield a fusible slag, conducting the volatile reaction products into contact with carbon heated to its temperature of maximum reductivity, continuously replacing the carbon and condensing the metal, substantially as described.

1,081,116.—SMOKE SEPARATOR. Clayton Floyd Holmes, Beaumont, Tex., assignor of one-half to Joseph Friebeis, Beaumont, Tex.

A smoke separator for smelter furnaces and like apparatus, comprising a cooling flume connected at one end with the apparatus, a suction fan connected with the other end of the said cooling flume, a series of connected and vertically extending cooling coils arranged transversely within the said flume to retard the passage of the smoke and gases through the flume and to cool the said smoke and gases, and a precipitating tank charged with a cooling medium and into which discharges the said suction fan.

1,080,862.—ELECTRIC ZINC FURNACE WITH INTEGRAL CONDENSER. John Thomson, New York, N. Y.

An electric furnace having a horizontal carbon resistor, two sets of terminals each comprising a plurality of carbon terminal members the inner ends of said terminal members being on contact with the resistor and located within the walls of the furnace, the outer ends of said terminal members being located in the walls of said furnace, and two sets of metallic strips which protrude from the walls to the exterior of the furnace, one set of said metallic strips connecting the outer ends of carbon members constituting one set of terminals and the other set of metallic strips connecting the outer ends of carbon members in the other set of said terminals.

FUEL-BRIQUETTING INVESTIGATIONS. By C. L. Wright. *Bulletin* 58. P. 277. Ill., plan, index. This covers the work done from July 1904 to July 1912. The amount of lignite coal in the United States, easily mined and suitable for briquetting, is estimated at 389,534,000,000 short tons, while the total easily mined and briquetted with difficulty is 1,087,514,400,000 tons. Briquetting has been done with great success in Europe for 30 years. Tests by the Bureau of Mines were made on lignite and other coals from several states. The machinery used, weathering tests, the fuel value of the products, and considerable other information, comprise a valuable record of the work done on this subject.

Industrial Progress

The Meridiograph

By LOUIS ROSS

Nearly all surveys of mines or claims require the determination of an accurate north line for reference, one that is more reliable than that given by the magnetic needle. The method of obtaining such a true meridian has been shrouded in a haze of technical mathematics and astronomy, requiring the services of a skilled surveyor; and to him this determination meant an evening's work in observing the North Star, or the solution of complex problems in spherical trigonometry. The costly solar attachment made for this purpose encumbers the transit and is none too accurate; therefore, engineers usually prefer to undergo the labors of star observations rather than trust to the attachment.

THE MERIDIOGRAPH.

I have devised an instrument which obviates all the difficulties mentioned, and have named it the 'Meridiograph.' With its aid a true meridian may be determined in a few minutes, at any convenient hour of the day, no computations, knowledge of astronomy, or the use of any tables or books being required. It is only necessary to measure the sun's altitude. Its declination is taken from the Ephemeris which accompanies the Meridiograph, and the latitude of the place is obtained from a map. The Meridiograph will then give directly the true bearing of the sun to an accuracy of about 1 to 2 minutes of arc, varying according to the time of day. In shape and operation the Meridiograph is like a circular protractor, seven inches in diameter. It consists of two discs rotating with respect to each other, and a reading arm. The data are set off on the proper scales by means of the reading arm, just like setting off angles on an arm protractor, and the true bearing of the sun is read directly. There are no mechanisms to get out of order. The general instructions provided will enable anyone who can read an angle on the transit to determine an astronomically true reference line at any time of the day. The skilled engineer will find in the Meridiograph a computing instrument which will accomplish in two minutes what would otherwise occupy an evening's work, or require the solution of a laborious problem in spherical trigonometry.

American-Ball Four-Cylinder Triple-Expansion Engine

A new high-speed engine for driving centrifugal pumps, built by the AMERICAN ENGINE & ELECTRIC CO., is of the triple-expansion type with four cylinders. A 1000-hp. engine using 250 lb. steam and 25-in. vacuum, of the double angle type, was recently built. In it the high-pressure cylinder and intermediate pressure cylinder are horizontal, and the low-pressure cylinders are vertical. This construction is claimed to give large ratio of expansion and therefore high economy, and to eliminate an enormous low-pressure cylinder with massive reciprocating parts. With a single large low-pressure cylinder, the speed would have to be materially reduced, and this would increase the size, weight, and space required by the engine. The increase in weight would, in turn, necessitate decrease in speed, so that if a three-cylinder triple-expansion engine is to be operated at high speeds usually desired for driving pumps, the size of the low-pressure cylinder must be reduced, with corresponding reduction in expansion ratio and economy. The difference in economy amounts to several pounds of steam per horse-power hour.

According to the manufacturer, the higher speeds may be used with the four-cylinder construction, because of the smaller size of the two low-pressure pistons and rods and because the inertia forces of the vertical reciprocating masses are opposed and balanced by equal and opposite forces from the horizontal cylinders. This advantage of the angle construction is now very well known, from the wide use of the American-Ball angle compound engine for driving high-speed electric generators, also the double-angle type of engine, especially adapted for direct drive of paper machines at high speeds. The four-cylinder triple-expansion engine is another application of the same design.

The speeds at which these engines are operated are considerably higher than those of three-cylinder engines in which economy is sacrificed to reduce the size of the low-pressure cylinder. Vibration and pounding are eliminated even at very high speeds, so that the foundations may be light and inexpensive. When this engine is installed on a dredge-boat, for instance, no special stiffening of the dredge is necessary, the engine being simply supported on a cradle of I-beams. For stationary plants, a simple block of concrete is all that is necessary, and this is far less expensive than the foundations needed for a compound Corliss engine of equivalent power. It is estimated that a 1000-hp. four-cylinder triple-expansion American-Ball engine would require about 25 cu. yd. of concrete for its foundation, while a compound Corliss engine of equal power would require 125 yd. of concrete, a difference of 100 yd., which at \$10 per yard would represent a saving in favor of the American-Ball angle-type four-cylinder triple of \$1000. The design of valves, pistons, cross-heads, rods, etc., of these engines is similar to that of the American-Ball angle compound engines.

The L. C. TRENT ENG. CO., INC., has issued Catalogue No. 2 containing complete descriptions of the cyaniding machinery made by this firm. Especially interesting data are given regarding the L. C. Trent underfeed agitator, which is to be known hereafter as the 'Carpenter type,' being named for J. A. Carpenter, superintendent for the Nevada Milling Co., who perfected the machine.

The Webster Method for March is devoted to coal-handling equipment, but this includes many devices that could be used to advantage around any large mine, mill, or smelter; picking belts, conveyors, bucket elevators, dust jackets for screens, cooling belts, unloading machines, and chain elevators especially.

WAGES in Australia still appear to be on the upward move. During 1913 there were 319 changes in all classes of trade, affecting 163,132 employees, who secured an average increase of \$1.08 per week per person. During the past 10 years or so, wages have been increased 15 per cent; but the cost of living has moved up about 25 per cent in the same time.

'MOTHER' JONES is reported as having recently smuggled out a message to 'General' Villa from the Walsenburg jail, where she is being held incommunicado. Whether this was an appeal for help in the settlement of the Trinidad affair or regrets for being unable to be present and take part in the Torreon campaign is not stated. However, this secret message to Francisco is undoubtedly like that to Garcia, of great import, and the public will watch the Constitutionalist leader's movements with added interest.

AN automobile whip is being successfully operated in northern Nevada. The whip is arranged just as it would be for a horse. However, this 'whip,' or 'whipsy' as the device is sometimes called, is for hoisting rather than for increasing acceleration. It consists of the usual overhead and ground pulleys through which the rope runs from shaft to roadway. When the hoisting signal is given, the car runs straight away from the shaft; when lowering, it backs until the rear wheels strike a bumper near the collar. Incidentally, the car is used for transportation to and from the mine.

UNION MINERA DU HAUT-KATANZA is again reported as about to embark upon elaborate improvements for increasing the smelter capacity and conducting operations on a greatly increased scale. Plans for four additional furnaces are being considered and with the general increase in scope of operation it is expected that the annual output will be over 30,000 metric tons of copper, which will place the property among the big copper producers. The holdings of the Company include one of the most extensive mineralized tracts which the industry knows, and, according to a recent report, ten mines have been sufficiently developed to prove 10,000,000 tons of 10 per cent copper ore. The concession comprises a district which is about 200 miles long and contains upward of 100 mineralized outcrops. Tin, gold, and platinum are also reported

in the district in profitable quantities. The difficulties encountered in the development of this tract were numerous, due chiefly to its remoteness from all bases of supply, but with the advent of railway transportation, development of fuel supplies, installation of coke-making equipment, and reduction plant the outlook is brighter. While there is no doubt but that the holdings of the Katanza company include many valuable mineral deposits, there have been many reports circulated regarding the status of the Company, some of which have been exaggerated and unduly auspicious. It will, therefore, be a relief to record the large production which is now anticipated.

MINING is considered a public use in various states, as a consequence of statute enactment. As a result, mining companies have the right to exercise the right of eminent domain and to condemn and purchase property for specific purposes as granted. The matter recently came up in Nevada in connection with the desire of the Goldfield Consolidated company to condemn land belonging to the Old Sandstorm Annex Gold Mining Company, for storage of tailing. In Utah, the case of Strickley *versus* Highland Boy Gold Mining Company was taken up to the United States Supreme Court and decided favorably to the right.

Progress of Flotation Litigation

Litigation has marked every step of progress in connection with flotation. Considering the complexities and uncertainties of the patent laws of this and British countries, and keeping in mind the probable value of monopoly patents for the next ten years, this is not surprising. Great inventions are not usually the result of one man's activity, nor are they accomplished by a single step. They mark the culmination of much experimental work on the part of many men, and in a sense they express the *zeitgeist* of the moment. Just as a great occasion has always, historically, seemed to find a fit man at hand, so a great metallurgical or mechanical need seems at the right time and place to call out the primitive spirit of invention that has brought man out from the stone age. There is always a final step, but under such conditions it requires nice judgment to apportion the credit, and the courts have a difficult task in determining the equities involved.

The ancients appreciated the affinity of oil for metallic minerals, though no serious effort to make use of this property in ore-dressing in a large way was made until well on in the nineteenth century. In 1860, the Haynes patent described a definite process for separating gangue from mineral by means of fatty or oleaginous material, but apparently the process was never applied. In 1886, Miss Everson proposed to make use of acid to intensify the differences in affinities of mineral and gangue for oil and water. It was not, however, until late in the nineties that serious and successful efforts to use flotation became general. Then there was a large crop of processes and patents, and in Aus-

tralia, especially, the competition between processes became keen. Fights, judgments, and compromises have succeeded, until now the situation is beginning to clear. A decision recently given by the Judicial Committee of the Privy Council, noted in our issues of March 14 and 28, establishes certain important boundary lines, and another decision, probably to be handed down next month at San Francisco by the Circuit Court of Appeals, is expected to set up other important guide posts. Unfortunately, owing to the fact that decision by a Circuit Court is not absolutely final, the American judgment may not end matters. In view of the importance of the case, the defeated party will naturally use every effort to bring the matter before the United States Supreme Court, and, while in patent cases that is not often accomplished, there is a possibility of such review. This is a less probable cause of trouble than the fact that another infringer, in another district, could precipitate another fight practically *de novo*.

Speaking in general terms, there are three classes of flotation processes now before the public; (1) film flotation; (2) bulk-oil rafting; (3) agitation-froth flotation. There are cross-divisions based upon heating or not heating the solutions, use or non-use of acid, the method of introducing air or generating gas in the mixture, and other minor points. There are also other processes, such as the Cattermole and the Potter, that apparently are applicable in special cases. There is, too, the ingenious Murex process which, while it uses some of the methods of flotation, introduces a wholly different principle and stands by itself. The Murex, by the way, is about to be introduced in North America by Mr. James M. Hyde, the designer and builder of the Butte & Superior mill, and one of the notable figures in the flotation litigation now under way.

Film flotation is simple in principle but difficult in practice. It depends upon delivering the finely ground gangue and metallic minerals upon the surface of the pulp by such a method that the valuable mineral does not break through the thin surface film, while the gangue does. It is in successful use in the Morning mill of the Federal Mining & Smelting Company in the Coeur d'Alene, where the Macquisten tubes are the particular apparatus adopted. There is little controversy about this process. Its failure so far to achieve wide use is due to the limited capacity of the necessary machinery and its limitations in treating slime. A slowly moving, little disturbed current of water is necessary, which seems incompatible with high capacity.

The oil-rafting processes are best exemplified by the Elmore, which was used in several countries and has found a number of applications. The Elmore vacuum process now in use involves different principles. In the oil-rafting process the metallic minerals are entrapped in a body of oil and are supported by it. The low specific gravity of the oil offsets the weight of the mineral, and the whole mass floats over a lip or other device to an outlet. It is the patent on this that has just been held valid by the highest British court upon appeal from New South Wales. As the question arose

over claimed infringement by Minerals Separation, operating the 'agitation-froth' process, it is interesting to note that the decision sustained the contention of the respondents that the expression in the patent at issue "the selective action of oil" was referable only to conditions in which the oil is present "in sufficient quantities to entrap or coat or absorb the metallic particles, and is of sufficient tenacity to carry these particles in the process of separation, whether by buoyancy or in the form of oil globules." This was held to be true whether the process be carried out in any of three sets of apparatus described. The importance of the latter lies in the fact that one apparatus described, provided for removal of the floated material by means of an oiled belt, and distinctly called attention to the fact that separation in this instance does not depend upon the buoyancy of the oil. The judgment of the British court apparently leaves the Elmore and Minerals Separation each free from the other, though it is to be noted that the Elmore vacuum process was not before the court. The processes adjudicated are held to be independent and, by inference, mutually non-infringing, so that competition must be upon the merits of each to meet particular situations that arise.

The agitation-froth process depends upon the lifting power of air bubbles whose walls are composed of particles of the mineral to be recovered, bound together by an extremely thin envelope of oil. Its utility rests upon the fact that large quantities of material can be rapidly and cheaply handled by simple machinery and that it is applicable to the fine slime that is lost in all forms of water concentration. Minerals Separation claims that its patents on this process are basic, and this, and the claim of infringement as against Mr. James M. Hyde and his associates at the Butte & Superior mill, were upheld by the District Court at Butte last fall, as we noted at the time. It was this case that was recently heard on appeal at San Francisco and decision of which is anticipated next month.

In the hearing, Mr. Hyde and his associates held that they were but using the knowledge of the prior art with skill and metallurgical knowledge. They cited particularly the Froment, Everson, and Kirby patents, and made demonstrations before the court, using amounts of oil varying from a fraction of one per cent to 25 per cent in treatment of Butte & Superior ores and producing in each case a froth. It was claimed that these demonstrations were under the terms of the Minerals Separation, Froment, Cattermole, and Kirby patents, and it was pointed out that the amounts of oil used were too small to cause bulk-oil rafting. To this, objection was entered on behalf of the Minerals Separation that the demonstration did not in fact reproduce the conditions defined by the patents cited, and furthermore that the froth produced, where the conditions departed from those of the Minerals Separation process, was not a true 'agitation-froth' but a different phenomena. It was conceded by all that the affinity of oil and oily substances for sulphides had been long known, and there seemed no disposition to

question the fact that Miss Everson discovered the usefulness of acid in intensifying the selective action of the oil. There was also no controversy over any form of film flotation or bulk-oil rafting. In the lower court much had been made of the Everson and Froment patents by Mr. Hyde and his associates. At the San Francisco hearing the Kirby patent was strongly urged as anticipating the Minerals Separation patent. This was taken out by Mr. Edmund Kirby shortly before the patent in litigation, and was based upon work done by him in British Columbia. The essential novel features were that he proposed to use a light oil, that it should be heated, and at one stage of the process he bubbled air into the mixture. He also specified violent agitation, and it is contended that this could not have been done without producing a froth, which is admitted to be the peculiar and distinctive characteristic of Minerals Separation flotation. It was also brought out that an excess of oil, in certain cases at least, did not prevent formation of a froth. They, therefore, contended that in the work at the Butte & Superior mill at Butte the metallurgists were merely using the common knowledge of the prior art with due effort to decrease consumption of oil. It was urged that in decreasing the amount of oil, Minerals Separation had not produced a new result, but had merely striven for economic efficiency, hence could not claim invention.

In reply, Minerals Separation presented an excellent and instructive history of the art. It was urged that the froth of 'armored bubbles' first produced by Mr. A. M. Higgins was a wholly new thing and not to be confused with the incomplete formation of bubbles in an excess mass of oil that was the best that could result from the Kirby process. The Froment process was illustrated, but held to be worthless, and the various bulk-oil processes were held to be uneconomical and proved by experience to be worthless in actual practice. As to the possible formation of a froth with larger quantities of oil, it was urged that the so-called froth was not a true 'agitation-froth'; that it was a mass of oil in which bubbles were entrained and entrapped rather than a mass of air bubbles of which the walls were formed by sulphide particles and in which the oil was so small an element as not to be determined except by analysis. Strong emphasis was also placed upon the fact that prior art had not in fact resulted in the treatment of ore in quantity, while the Minerals Separation process went at once into actual use and had resulted in establishment of a new industry. Incidentally, it was brought out that the earlier processes made no attempt to treat slime.

It will be extremely interesting to see how the Court of Appeals rules upon this case. While minor points have been raised as to the validity of the patent, apparently the decision must rest in the main upon the court's determination whether as a matter of fact the 'agitation-froth' of the Minerals Separation process is different from the oil 'magma' of the Froment or the aerated oily mass of the Kirby and similar processes.

Levee Building With Bucket Elevator Dredge Equipped With Stern Delivery Stacker

By C. G. LEESON

The Oro Water, Light & Power Co.'s 5-ft. gold dredge *Hunter* has just completed a strip of tailing bank 1700 ft. long on the Feather river about five miles below Oroville. The Feather at this point makes a long bend and the erosion of the south bank, due to very swift water, has encroached upon the Marysville and Oroville county road to such an extent that it had been necessary to rebuild the road close in and skirting the high bluff which borders the river. A bulkhead made of piling and three-inch plank, 20 ft. high by 800 ft. long had been built by Butte county in an attempt to turn the current away from the road. During the high water of this year this bulkhead was washed away and the bank had caved to the edge of the roadway. Another high water period would have destroyed the road and necessitated a new road on top of the bluff with consequent heavy grades.

The Oro company was moving the dredge *Hunter* to a property lower down on the river and by an agreement between Butte county, the Anti-Debris Association and the Company, an arrangement was made to dredge the bed of the river, with the understanding that all gravel recovered was to be piled upon or close to the road side of the river. It was expected that the gold recovery would pay for the operations so that

the work could be done without expense to the county. Incidentally the gold failed to materialize in paying quantity. The work was, however, done free of all charge to the county.

The original plans were made so that this work in the current would be done during low-water time, since at the point where the river approaches and parallels the county road the current becomes in flood times very swift and very dangerous. During the January flood of this year, just prior to commencing the work, the river rose 20 ft. The dredge was delayed in its progress and did not enter the river until February 1.

Due to the probability of extreme current and to the fact that the flotation of the dredge had decreased due to age and concrete repairs to the hull, so that in certain conditions of operation the free board at the stern was entirely lacking, it was decided to build a pontoon to increase the stern flotation and to decrease the current resistance of the stern. The figure below

DREDGE IN DANGER FROM CURRENT.

WOODEN BULKHEAD BUILT TO PROTECT ROAD.

SECTION THROUGH PONTOON.

shows this pontoon as constructed. It contained 12,000 ft. of lumber and figured net 54 tons flotation. When placed and the water pumped out it raised the stern of the boat 2 ft. above its previous position. The design is such that the battered back, when the current pressed,

LEVEE AS BUILT ALONG COUNTRY ROAD.

tended to elevate rather than to depress the stern. The portion which went under the hull was of such capacity as to balance the upright portion around the stern bottom corner of the hull. The width of the portion going under the hull was 7 ft. greater than the upright portion. This shelf was utilized in sinking the pontoon under the dredge. Ten tons of sand in sacks was loaded on each of these projections. The whole structure

was then pumped full of water and floated under the dredge and when in place the sand was dumped and the pontoon then hugged closely the bottom of the hull. It was leashed with cables as safety precaution.

During the high water of February 17 and 18, the river came up 13½ ft. in 24 hours. The dredge was caught at that time in a most disadvantageous position. The current was such that the water piled up

FALLING PILE LEVEE AS COMPLETED.

BUCKETS AND DREDGE BOW OPERATING IN SWIFT CURRENT.

behind the pontoon approximately 2 ft. Had it not been for the protection and the additional flotation provided by the pontoon, it is believed by the operators, the dredge would have been swamped. A view herewith, showing the very precarious position of one of the Guggenheim dredges when moving in the current of the river and when the current rushed over the deck, is shown as of interest in this particular point.

The method of operating the dredge to build the levee or protection bank is new. The work done proves that a side delivery stacker is not necessary for work of this character. Advantage was taken of the fact that the water was of such depth on the bank side that it was unnecessary to dig flotation clearances on that side. The dredge was operated on the single-cut side-step principle. Spuds were used. The out-swing was made to a position at right angles to the bank; the in-swing to a position parallel to the bank. Bedrock was reached at varying depths from 22 to 37 ft. Under ordinary river conditions the depth of water before digging varied from a sand bar showing above water to 15 ft. deep. The dredge was 40 days in making the passage. This time included, however, seven days 'shut-down' while the boat was tied up, stern up stream, because the current was so swift that the side-line winch was unable to swing the boat against it. During the 40 days the dredge handled 135,000 cu. yd. Figures herewith show the character of the bank before dredging commenced; the pontoon, the swift current encountered, and the very effective protection levee built.

A new mining law has been discussed by the New Zealand Government, which includes regulations on the following: ventilation; strength of ropes used in hoisting; safety cages; the use of explosives; supply of water for laying dust made by drilling or blasting; change houses with hot and cold water, baths to be installed when demanded by a certain percentage of men; additional powers to be given to employees' inspectors employed by any miners' union at the expense of the union, such as reporting on the dangerous parts of mines; men must be immediately withdrawn from

workings containing gases; miners who have contracted fibrosis or lung troubles from dust shall be entitled to benefit from the miners' relief fund equally with men who have suffered injuries from accident; hoisting engineers must be examined annually by a medical man; and the Minister of Finance in the government is empowered to obtain not over \$96,000 per year and advance this money to mining companies for development work.

Accidents and Personal Injuries*

1. In case of accident, however trivial, or of personal injury, however slight, received or sustained in the course of duty, an injured employee must give immediate notice, or cause immediate notice to be given, to the Company. Such notice may be given by an employee to his foreman, or to the Company's surgeon, and must be given at the time of or immediately after the happening of the accident, to enable the Company to investigate the causes and circumstances of the injury, to determine whether it is accidentally inflicted, and that it renders the employee unable to perform his duties in the service of the Company.

2. All employees injured in the service of the Company must obey the surgeon's instructions in reporting for examination, using the remedies and following the treatment prescribed, and going to the hospital if directed.

3. All employees who are disabled but not confined to the house, must report in person at the surgeon's office, from time to time, as reasonably requested.

4. Failure on part of an employee to give immediate notice, as above directed, or refusal to obey the surgeon's instructions, will be deemed sufficient cause for dismissal.

Copper production of Peru in 1913 was 27,940 metric tons, made up as follows: bars, 20,340; matte, 4462; and shipping ores, 3138 tons. This is an increase of 100 long tons on the previous year.

Electrical Driving of Winding Engines

By C. ANTONY ABLETT and H. M. LYONS

*The use of electrical machinery for driving hoisting engines in mines and reversing rolling mill plants in steel works is comparatively recent, the first winders of importance having been introduced in 1902. The earlier winding engines were extravagant in power and had the disadvantage of drawing very heavily upon the source of electrical supply at the moment of starting. It was, therefore, impossible to use them on systems where the supply of current was limited, and even on comparatively large plants their use resulted in serious interference with other machinery. These disadvantages were, however, practically done away with when the Ward Leonard system and Ilgner's adoption of the flywheel to this system were introduced, but the past few years have seen greater improvements in the Ward Leonard and the Ilgner system. The present paper will deal chiefly with the developments of these systems by the various Siemens companies, who have installed about half the total plants in existence, and with whom the authors have the honor to be associated.

Ward Leonard System

In this system, Fig. 1, a direct current motor is used to drive the winding engine or rolling mill, the motor

FIG. 1.

being supplied with power from a direct-current dynamo, and the essential feature of this system is that the voltage supplied to the motor, and consequently the speed of the motor, is controlled by controlling the field current of the generator, instead of by varying the resistance in the armature circuit of the motor. Thus, as the field current of the generator is increased from nothing to a maximum, the motor speeds up from standstill to full speed, and if the field current of the generator is reversed, the motor reverses its direction of rotation.

This system enables a very exact control of the

speed to be obtained, because the speed of the motor is practically proportional to the strength of the generator field, whatever the load on the motor may be, while with any control system where resistances are inserted into the armature circuit of the motor, the speed would vary within very wide limits with a change of load, rendering the exact speed control quite impossible. The control of the dynamo field involves scarcely any waste of electrical power, but where resistances are inserted into the armature circuit the loss of power may be, and usually is, very great. The field currents of the generator are small, so that the control mechanism is small, compact, and very easy to handle, the armature currents are perhaps fifty times as great, so that any control mechanism which varies the resistance of the armature circuits is large, clumsy, and difficult to handle, in fact a complicated relay system is often necessary to enable it to be handled at all.

The dynamo used to supply the motor in the Ward Leonard system is usually driven by a motor supplied from the available power circuit, forming a motor generator set, and this motor may be either direct current or three-phase, according to the power available. The dynamo may be and sometimes is driven by an engine, water turbine, or other prime mover, if this happens to be more convenient.

The main control lever for operating the winding engine is coupled to the regulating resistance in the field circuit of the generator so that when this lever is in the mid-position there is no current in the generator field. As the lever is moved in one direction the generator field current increases, and as it is moved in the other direction the generator field current is also increased, but in the opposite sense. From what has been said in the introductory remarks it will be seen that when the lever is in the mid-position the winding engine is at

a standstill, and that it starts and speeds up as the lever is moved from the mid-position in one direction, while if the lever is moved from the mid-position the other way the winding engine increases in speed in the other direction, and that the speed of the winding engine is practically proportional to the displacement of the lever from the mid-position, and is not affected by the weight of material being hoisted.

The driver does not have absolute control over the speed, for two cams are provided on the depth indicator, one for each cage, which operate levers coupled to the control lever in such a way as to prevent the cages being accelerated at too rapid a rate, and to slow up the winding engine at the proper point so that the top is approached at a crawling speed. Pro-

*From a paper on 'Electrical Driving of Winding Engines and Rolling Mills,' read before the Canadian Society of Civil Engineers and the Canadian Mining Institute.

vided that these limits set by the cams are not exceeded, the speed of the wind is entirely within the driver's control. To slow up the winder and bring it to a standstill, the control lever is brought back toward the mid-position, thereby reducing the field current of the generator, and reducing its voltage below the voltage of the winding motor, so that the current between the motor and the generator reverses and the winding motor gives back power to the generator, thus producing a strong electric braking effect. The more rapidly the lever is moved backward toward the mid-position the stronger the electric braking effect will be.

The kinetic energy of the moving parts of the winder is converted to electrical energy and returned to the system. The lever may be brought toward the mid-position to produce this electric braking effect, either by hand or automatically by the cams, as mentioned above. The depth indicator and the cams are positively driven from the drum of the winding engine and the cams are so geared that they make less than one revolution per wind.

Fig. 2 shows the typical horse-power diagram for a

FIG. 2.

winding engine. The inertia of the drums, cages, head sheaves, material wound, and the ropes, which altogether weigh about 60 tons in this particular case, necessitate a horse-power at the end of the acceleration period of each wind of 1865, which is about three and a half times the average power demand of the winding engine, in this case 524 hp., and it is found that the maximum acceleration peak is usually between three and four times greater than the average demand.

The consumption of energy for this Ward Leonard control rises gradually during the starting period, and

the maximum is only reached at the end of the time of acceleration, from 10 to 15 seconds after the start, because the speed of the winding motor is increased while it is giving the requisite turning moment by increasing the field of the generator, and consequently there is no loss of power in starting. Since this acceleration peak is of short duration and only comes on gradually, it is possible to supply Ward Leonard winders from power stations of comparatively small total output, provided that the machines in the power station have a sufficient overload capacity to maintain their speed during peak loads, as is usually the case with steam turbo-generators where the generators are provided with modern voltage regulators.

Where, however, this is not the case, and the acceleration peaks of the winding engine are large compared with the average demand on the power station, or where the winder is supplied through a long transmission line from a distant power station, it is sometimes necessary to couple a flywheel to the motor generator set. In this case provision must be made so that during a peak load the motor generator falls in speed, enabling part of the stored energy of the flywheel to be used to supply the heavy demand, and when the load is small the motor generator set is speeded up again, the surplus power being taken to restore the energy of the flywheel, so that the demand from the power house or supply system is maintained at about the average. This is the Ilgner system, so-called after the engineer who first used it in practice.

Fig. 3 illustrates the effect of the flywheel in equal-

FIG. 3.

izing the load taken by the winder, where it will be seen that the current taken by the winding motor varies between +1900 and -1000 amperes, while the current taken from the supply system is maintained practically constant at 400 amperes, the maximum voltage supplied to the winding engine and the supply voltage being the same.

Three-phase motors are usually used to drive the motor generator sets supplying winding engines, and their speed can only be conveniently varied by inserting resistance into the rotor circuits, which causes a loss of power. In addition to this a certain power is

required to drive the flywheel to overcome the friction and windage loss, so that while the use of the Ilgner system prevents peak loads being taken from the supply system or power house, it entails a certain loss of power. In many cases the cost of this loss of power, which is justified by the benefit of the steady load to the supply system, which improves the economy and voltage regulation of the power house, may avoid the installation of extra plant in the power house, or where the winding engine is being supplied through a long transmission line, will enable a cheaper transmission line to be used than would otherwise be the case, and will improve the voltage regulation of this transmission line.

The Ilgner System

The following example will give an idea of the power taken by the Ilgner system under practical working conditions with a winding engine arranged to wind 240 tons per hour from a depth of 1960 ft., making as a maximum $44\frac{1}{2}$ winds per hour, where the flywheel is used whenever the full output is being wound at the full speed, but where a lesser output is being wound at reduced speed, so that the acceleration peaks become less serious, the flywheel is uncoupled to save power. These results are conveniently expressed in terms of the kilowatts taken by the electric winding engine plant per shaft horse-power.

| | Output in tons per hour. | Kw. per shaft horse-power. |
|------------------------|-----------------------------|-------------------------------|
| With flywheel | 240 | 1.49 |
| " " | 160 | 1.60 |
| " " | 108 | 1.77 |
| Without flywheel | 160 | 1.35 |
| " " | 108 | 1.48 |

It will thus be seen that when working the winding engine on the Ilgner system there is an increased loss of power of from 16 to 17%, as compared with the Ward Leonard system, and naturally with the latter, where the flywheel is uncoupled, the resistances are cut out of the rotor circuit of the three-phase motor to avoid loss of power.

To avoid misunderstanding of the above results, it should be specially pointed out that shaft horse-power is taken to mean the actual work done in raising the load, that is, if the actual weight of coal or ore, expressed in pounds, which is raised per minute is multiplied by the depth of the shaft in feet, and divided by 33,000, the shaft horse-power is obtained. The shaft horse-power thus does not include the mechanical friction of the winding engine, the sheaves, the guides, or the rope losses, and the figure of the kilowatts divided by the shaft horse-power brings in the mechanical efficiency, as well as the electrical.

To enable the speed of the motor generator set to be automatically reduced so that the flywheel may give up part of its stored energy, the three-phase motor of this motor generator set must be of the slip-ring type. The slip-rings are connected to the automatic or intermittent slip regulator which inserts resistance into the rotor circuit when the speed is to be reduced. This

slip regulator usually consists of liquid resistance in which are immersed plates connected to the slip-rings, and it is operated by means of motor relay supplied by current from a series transformer connected in the circuit of the main three-phase supply, so that when the speed is to be reduced, the immersion of the plates is decreased, increasing the resistance between them, and when the speed is again allowed to rise, immersion of the plates is increased.

The series transformer is usually supplied with tapings connected to a dial switch so that the average load maintained by the slip regulator can be adjusted to the work which is being done by the winding engine.

Flywheels are usually designed to equalize the load by falling in speed from 15 to 20%, and it is found that this entails a loss of power in the slip regulator of about 7½ to 10%. The flywheel is usually coupled to the motor generator set by means of flexible coupling, though in some very recent Ilgner motor generator sets, where there happens to be no advantage in running with the flywheel uncoupled, the electrical machines and the flywheel are arranged to be carried by two bearings only, reducing the first cost and the friction losses.

Capital Cost

Of recent years the capital cost of Ilgner plants has been greatly reduced, owing to the adoption of higher speed for the motor generator sets and to the improvements in the manufacture of such flywheels, which enable them to run at very high peripheral speeds compared with those used in the earlier winding engines. For example, the provision of flywheel capacity to equalize peak loads of 60,000 hp. seconds, in the ordinary days of Ilgner winding, where peripheral speeds 15,000 ft. per minute were used, would require two wheels of a total weight of about 80 tons, the friction and windage loss of which would be about 150 hp. Under modern conditions where the regular peripheral speeds are 27,000 and 30,000 ft. per minute a single flywheel of 22 tons weight would be used, instead of the two flywheels having a total weight of 80 tons, and the friction and windage losses would not exceed 100 horse-power.

A sheet metal casing is usually placed outside the rims of the flywheel to reduce the windage loss of the flywheel to a minimum, and this is found to be sufficient for the purpose, because practically all the windage loss is caused by the outside surface of the rim, the web producing very little windage. This can be shown in a striking manner by holding a handkerchief against the web near the inner surface of the rim while the flywheel is running, there being scarcely enough wind to blow the handkerchief out.

The Ilgner system was used on practically all the early European winding engines, but as at the present day power stations are being installed of much greater capacity than those of a few years ago, and high-speed turbo generators of large overload capacity are being adopted, the Ward Leonard system at the present time

is being used to a **much** greater extent than the Ilgner system for winding engine work. Generally speaking, the Ilgner system of winding may be preferable to the Ward Leonard system in the following cases: (1) when the time occupied by the wind is short; (2) for vertical shafts; (3) for large outputs; (4) where the winding speed is very high.

Comparisons

The above conclusions may be considerably modified by the nature of the electrical supply. Where the power station is small or the winder is supplied through a transmission line of considerable length, the Ilgner system will be more suitable, but where the power station is large and near the winder, the Ward Leonard system is the better. Where power is being purchased from a supply company the choice of system would be very greatly influenced by the method of charging adopted by the supply company and by their regulations as to the permissible overloads and the amount of disturbances which they will permit to the regulation of their system. It is always advisable to consider each case on its own merits. Where there are a number of winding engines supplied from the same power station the Ward Leonard system would prove very suitable, because the combined effect of these winding engines working together will be to reduce the percentage of fluctuations on the power station load.

The mechanical brake is so arranged that when it is required to bring it into action it is actuated by a weight at the end of a lever, but it is normally held off the drum by an air cylinder. Under normal conditions the cams on the depth indicator actuate the control lever, so that the cages approach the top at a very slow speed. When they reach the top the driver brings them to rest by means of his control lever, and then puts on the mechanical brake to hold the cages in position by means of the brake lever. The brake lever is interlocked with the control lever, so that the driver cannot put on the brake by means of the brake lever until the control lever is at about the middle position, that is, unless the cages are moving at a comparatively slow speed.

To enable the driver to stop the winder in case of any emergency arising, a third lever, the emergency lever, is placed on the driver's platform and if this is operated it puts on the mechanical brake through the emergency gear and at the same time cuts off the excitation from the dynamo of the motor generator set. A throttle valve is fitted to the air cylinder to prevent the air from escaping too rapidly, so that if the mechanical brake is put on through the emergency gear it takes a second or two to apply it with full force, and damage would not be caused by the winding engine being pulled up too rapidly.

From what has been said above, it will be seen that the brake is applied by the positive action of the weighted lever, and if the air pressure should fail the brake is promptly put on. The armatures of the wind-

ing motor and the generator are permanently connected by heavy cables, and there are no cut-outs or switches in this circuit, so that the circuit between the armatures cannot be interrupted; electrical braking is always available as well as the mechanical brake, unless the excitation should fail. To protect the electrical machinery and the winding engine against undue overloads an overload relay is connected in this circuit between the armatures, which if brought into operation cuts off the excitation from the dynamo and puts on the mechanical brake through the emergency gear.

As mentioned above, cams are provided on the depth indicator which keep the acceleration within safe limits, and the cage is brought gradually to a slow speed by the time it reaches the top. An overwind device is provided, usually both on the depth indicator and in the shaft, which puts on the mechanical brake through the emergency gear and cuts off the excitation should the cage overwind the bank, thereby bringing the winding engine instantly to a stop. Should the air pressure or the excitation fail, the mechanical brake is put on by means of the emergency gear. If the motor generator set should speed up when a load is being lowered and energy is being returned to the system by the winding motor, either owing to the circuit breaker in the supply system coming out or to the demand for power from the system being insufficient to absorb the energy being returned to the system by the winding engine, then the excitation is cut off and the mechanical brake is put on through the emergency gear. When men are being hoisted the throw of the main control lever is limited by means of a switch on the bank, so that the winding engine cannot be run above a certain speed.

Safety Devices

Where electrical driving is adopted it is very easy to provide safety devices, and all those mentioned are designed to protect the plant against careless handling, but if the majority of safety devices were dispensed with, the Ilgner and the Ward Leonard winder would still be better protected against careless handling than the steam winder. The fact that it is impossible for an Ilgner or a Ward Leonard winder to race or run away makes it inherently safer than the steam winder.

Gold output of Indian mines in January was as follows:

| | Tons. | Value. |
|---------------------------|--------|---------|
| Balaghat | 3,600 | \$1,424 |
| Champion Reef | 18,070 | 11,520 |
| Hutti (Nizam's) | 3,100 | 1,610 |
| Jibutal (Anantapur) | 1,010 | 245 |
| Mysore | 25,850 | 19,562 |
| Nundydroog | 7,500 | 6,715 |
| Ooregum | 12,908 | 7,758 |
| North Anantapur | 2,000 | 934 |

The output of zinc concentrate at Broken Hill, New South Wales, by flotation processes, was responsible for nearly 90% of the gain in the world's production of spelter from 1906 to 1911.

Properties of the Russian Mining Corporation

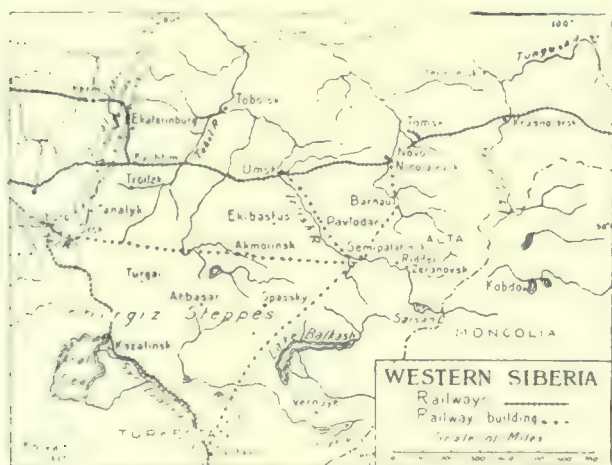

The organization of the above Company was explained in a London letter in the 'Special Correspondence' portion of this journal of February 14, 1914, and further information has been given out to the press by the directors, dealing with the properties to be developed. Among these, the Company has acquired an option on one-half of an anthracite coal mine in Central Russia, which is now being worked at a profit. It has also secured from Prince Alexander of Thurn and Taxis an option to purchase the rights of two concessions, and is at present directing operations at the two principal mines. Two engineers are now on their way to the property to decide on the first work to be done in the way of unwatering and opening the lower levels, and starting drilling work. Diamond-drills will be sent in after the opening of navigation on the Irtysh river in May; and it is anticipated that valuable information as to the extensions of ore-bodies can be obtained more quickly by boreholes than by underground prospecting. The nature of the ore-deposits lends itself to satisfactory exploration by drilling, as proved by the excellent results quickly obtained by the Russo-Asiatic Corporation on the Riddersk mine. A full geological examination of the concessions in connection with the ore occurrences will be started in May.

The Altai concessions were also described, the notes having been compiled partly from official records of

There are three principal mines of the country which give their names to the three original concessions, namely, the Zminogorsk, the Riddersk and the Zeranovsk. These, though a long distance apart, are in one general line of occurrence, northwest and southeast, and seem to exist under nearly identical geological conditions. A great number of smaller mines and prospects occur on the same general line of country. There are a number of abandoned copper mines in another parallel line nearer the Irtysh river and on the Zminogorsk concession. The ores of the mines mentioned are similar in general character and geological occurrence, but with local variations in the form of orebodies.

Zminogorsk Mines.—This property is probably the oldest, and was the most important in the country; and it is at present being worked as a gold mine. Full descriptions of this, and of some of the other mines to be mentioned, are to be found in a report made in 1869 by Von Cotta, the well recognized authority on the occurrence and origin of ore deposits. Von Cotta draws favorable conclusions as to persistence in depth of the ore-bearing vein from the fact of its proved length of over 5½ miles. One barite body was 300 ft. long, varying from 50 to 250 ft. in thickness and worked on to over 600 ft. in depth. More recent development has shown that the underlying hornstone carries finely divided galena, zincblende, and iron and copper pyrite, with gold in profitable amount. At one time more than 1000 miners were working in one large open cut. The portion of the ore treated for gold is reported to have yielded \$8 to \$10 gold per ton of ore by a simple process. With depth, difficulty in treatment arose; and at present a 15-stamp mill is in operation, with an experimental cyanide plant, to improve extraction, which was of late unsatisfactory, although giving returns above actual working cost. Reports of late results are encouraging. On the Zminogorsk vein about 25 mines have been worked at different times, and it seems evident from the records that on the dumps and developed underground there must be large quantities of ore, which, with an economical mining plant and modern metallurgical methods, would yield profitable returns. Recently some engineers have considered that the important ore-shoots have direct relation to certain anticlinals in the folded strata.

Zeranovsk Mines.—This group is about 150 miles south-east of Zminogorsk. It was opened in 1791, and in fifty-eight years had produced about 400 tons of silver and 10,000 tons of lead. After 1850 the production increased largely for some years. This was a very important mining centre, and had an established School of Mines at one time. The principal mine is developed quite extensively underground, where complex ores are found in depth. Estimates made in 1904 for the Rus-

the district, and partly from reports of several mining engineers, who have examined the various mines from time to time since 1845. It is stated that the original grant was of three separate concessions, covering the Zminogorsk of about 12,292 miles, the Riddersk of about 3073 square miles, the Zeranovsk concessions of about 2195 square miles. About two years ago the Riddersk was relinquished by the concessionaires, and has since been granted by the Russian government to the Russo-Asiatic Corporation, so that the property now under consideration consists of the Zminogorsk and Zeranovsk concessions.

sian government show about 150,000 tons developed and 50,000 tons on the dump. The ores were reported to contain about 22% zinc, 12% lead, 2% copper, 15 oz. silver and \$5 gold, equal to a total gross metal value of about \$48 per long ton. All the richer oxidized ore had been worked out to a depth of about 300 ft. but developments extend to 700 ft. in depth. The occurrence of the ore in the upper workings seems to have been in large lenses; but it is reported that at the bottom of the mine there are two well-defined veins of the base ore, each about 7 ft. thick, and proved over a length of fully 2000 ft., with ore at both ends. Occasional branches of rich gold-bearing quartz run off from these veins. The country rock is reported to be crystalline schist. Ore-bearing hornstone also occurs. In the neighborhood of the Zeranovsk mine there are a number of others, some carrying silver and gold, others producing more copper. There are occurrences of copper in porphyries, which may be of great value as concentrating propositions. There are more than ten abandoned copper mines in the Zminogorsk concession running in a general line northwest from the Irtish river. They were worked irregularly during a great many years, and the ores had to be transported by horse conveyance to Barnaul, a distance of about 250 miles, in order to be smelted. All the evidence available seems to show that changes in conditions and cost of working led to stoppage of these mines, so that their reopening and development would be very advisable if smelting works are established on the Irtish river, as is possible now that coal and coke supply is being provided for by new railway transport. Reports recently received from Zeranovsk state that the Putinzeff and Buchtarminsk mines can, with little development, be made to yield sufficient rich copper ore to justify some smelting operations with the base ores of the Zeranovsk mine.

Ore Treatment—There seems to be no doubt as to the various mines of the two concessions being capable of yielding a large tonnage of base-metal ores containing gold and silver and, of hornstone gold particularly, while there is evidence for the future profitable working of some of the copper mines. The point of immediate importance for the starting of profitable mining is that of the treatment of the ores, since it is clear that the present idleness of the mines is due to the absence of successful reduction works and not to lack of ore. The problem of treatment requires investigation and the consideration of all local conditions. Mr. Von Gernet, who is at present acting for the Russian Mining Corporation, was employed by the Imperial Cabinet in 1910 to examine the original three concessions, with a view to reporting on the possibility of working the complex ores. Several hundred tons of ore were taken from the dumps of the Riddersk and Zeranovsk mines, and average samples of these were sent to Germany, France, England, and the United States for testing by various processes. The results were such as to satisfy Mr. Von Gernet that modern metallurgical processes would be equal to profitably working the ores

from both mines when properly situated central works were established. His conclusion as to the ore of the Zeranovsk mine was, that a working profit of about \$14 per ton would be obtainable by well-known processes, while a better system would doubtless be elaborated before long to utilize more fully the various metal contents, and so increase the profit per ton. A chlorination plant was at one time put up, but was unsuccessful. The hornstone gold ores should be susceptible of an early solution of the treatment question and should permit of extensive operations.

A cable issued at the end of last week by the Russo-Asiatic Corporation gave the assay of bore-hole C at the Ridder mine, showing an average for the 112 ft. of solid sulphide in the hole of 33.4% zinc, 17.9% lead, 1.3% copper, 12.5 oz. silver, and 9 dwt. gold per long ton, representing a gross value in Russia of nearly £16 per ton. J. P. Hutchins and E. D. McDermott are now at the Altai concessions.

Pumping at the Gold Hill Mines on the Comstock

The equipment at the C. & C. shaft of the United Comstock Pumping Association was described in this journal of August 23, 1913, by A. M. Walsh. At the Gold Hill portion of the lode, the Sturges group of mines, namely, the Crown Point, Belcher, and Yellow Jacket, are working jointly. The following description of the pumps is from the report of George S. Sturges:

The two sinking pumps above referred to are of the direct connected electrically driven type and were made by the Byron Jackson Iron Works. Each pump and motor is mounted on a one-piece cast iron base supported on a 24-in. gage track by two trucks having four wheels each and connected to base by king bolts. The complete pumps proper are made of solid acid resisting bronze and shafts are bronze covered where they come in contact with the water. Pump cases are made in two parts, the upper half can be removed without disturbing the lower part or connections. Main centre bearing between each pump and motor is grease packed and water cooled by circulating jacket. The thrust bearing on pumps, also on motors, is oil lubricated, and metallic packing is employed on upper pump bearing. Hess-Bright bearings are used on motors and are lubricated by circulating oil system. These bearings also have metallic packing. Motors are each 200 hp. and are of the squirrel cage, induction, constant speed type, requiring 440 volts, made by the Westinghouse company, while the Byron Jackson company furnished the 'heads' and bearings.

Each pump has a rated capacity of 1500 gal. under head of 315 ft., allowing for pipe friction, and makes 1200 revolutions per minute. On account of delay in getting part of the equipment, it was impossible to test installation until December 20, when one pump was run a few minutes and it was demonstrated that it could pump water considerably faster than it ran in at that

particular point, and do it while sucking the water 12 ft. along the incline. The length of suction has been doubled. The plant was not fully ready to start until December 30. A severe storm the next day interrupted the electric service to such an extent that an actual start could not be made until the year 1913 had expired.

Two 10-in. wire-wound wooden pipes are used between pumps and 14-in. wooden pipe-line which starts at the 1400-ft. station and makes connection with the old steel pipe in Crown Point drift to Sutro tunnel. Commencing at east end of this steel pipe, which is 1200 ft. long, there is 1000 ft. more of the 14-in. wooden pipe connecting with box in Sutro tunnel. There is approximately 3000 ft. of pipe between 1400-ft. station and joint incline and box in Sutro tunnel. Most of this is run through new drifts and cross-cuts or through those which were reopened and repaired.

Pumps are handled by an electric winch to which an auxiliary power may be attached for use in emergency. A hoist placed in the incline at 1300-ft. level permits handling both waste and ore through this level from the lower levels of the property.

Discovery of Zinc in America

By CHARLES R. KEYES

Notwithstanding the facts that zinc is the last of the common metals to come under the complete control of mankind and that as a chemical element the date of its recognition is scarcely 200 years back, some form or other of it, as an earth of peculiar yet distinctive composition, is known to have been in use in the arts for a period of more than forty centuries. The circumstance that Greek coinage dating 1000 to 1500 years, B. C., contains a definite proportion of zinc, so large as 25% in some instances, indicates clearly that it was at this remote time utilized in alloy.

In this country the zinc industry is of so recent origin that its beginnings are still well within the memory of men living. Yet the existence of the metal appears to have been very early known. Mention of the ore for the first time seems to be almost, if not quite, as soon as that of lead. Unlike the case of the last mentioned metal zinc never had that great advantage of being sought for ammunition, the provision of which was so vital a problem to trapper and pioneer in the New World. The earliest record of the ore or metal is usually regarded as that of John Bradbury, an officer, who, investigating the resources of this country in the interests of England, traveled in 1810, through the Louisiana Purchase country, as the region west of the Mississippi river was then called. In the same year zinc was described and analysed from the Franklin furnace.

There appears, however, to be a distinct reference to an American occurrence of zinc very much earlier than any other heretofore specifically noted. In 1655 a French adventurer in the service of England, Pierre Radisson by name, and his brother-in-law, Médard

Grosielliers, visited the Indian tribes dwelling in the neighborhood of what is now Dubuque, Iowa, and spent the season in hunting and exploring mainly on Iowa soil.

Although Radisson's descriptions are very quaint they are at the same time entirely lucid. In the course of his account of the resources of the region he says that "In their country are mines of copper, pewter, and lead. There are mountains covered with a kind of stone that is transparent and tender and like that of Venice." The special mention of pewter without question refers to no other metal than zinc. It will be remembered that this term is the old English title for spelter (German and Dutch *spiauter*, Dutch *piauter*, English pewter), and that the name was applied in those days to both the metal and its ore.

That Radisson's reference does not allude to any mineral but zinc is conclusively shown by a number of circumstances. Drybone is a common associate of the galena ores of the district; and it would be easily recognized as the 'pewter ore' of England with which the explorer must have been well acquainted. In Colonial days, also, pewter plate was an important possession of every pretentious household; and the finding of the substance at these mines naturally made a profound impression on an active mind, an excitement second only to that of a gold discovery.

At the time of Radisson's sojourn at the Dubuque locality lead mining had already begun. The mineral had indeed at this time been taken out during a period of more than two decades—ever since the famous visit of Jean Nicollet, in 1634, who in the interests of the fur trade had introduced fire arms among the Indians and with them created an active demand for ammunition. A main reason for Nicollet's turning back at point rather than going on in his great quest of the South Sea and a short route to Cathay as he had set out to do, may have been this very discovery of lead deposits affording an unlimited supply for bullets.

Of the three widely separated localities in which lead was mined in this country previous to 1650, the Dubuque field is the only one so far as is now known in which zinc ore occurs. That zinc should be thus early recognized so long before it was actually used on a large scale elsewhere is a fact of some interest.

Tonnages Through Ship Canals

The following table shows the relative business of the principal ship canals of the world in 1912:

| | Tons. |
|--------------------------------------|------------|
| Sault Ste. Marie (Soo) 8 months..... | 79,718,344 |
| Suez | 20,125,120 |
| Kaiser Wilhelm (Kiel)..... | 7,580,000 |
| Manchester | 5,339,884 |
| New York State (Erie) 8 months..... | 2,606,116 |

The two American canals are frozen during four months of the year. Suez is a sea-level canal. The Kaiser Wilhelm locks have a larger capacity than those at Panama.

The Mineral Resources of the Harney Peak Pegmatites—II

By VICTOR ZIEGLER

The general facts as to the distribution and mode of occurrence of the rare minerals of the Black Hills have already been given,* as also special descriptions of the mica and tin deposits. It remains to describe the tungsten, lithia, columbite, and minor miscellaneous minerals.

Tungsten Deposits

The first attempt to utilize tungsten ore was made in 1906, when the Reinbold Metallurgical Co. shipped three carloads of ore (mostly huebnerite) from its mine on Sunday gulch, southwest of Custer. The American Tungsten Co., organized in 1907, erected a small mill on claims about three and a half miles east of Hill City. The Company had practically no chance to produce ore, as it was almost immediately involved in lawsuits, the mill and buildings were attached by laborers' liens, and it went into the hands of a receiver. The mill was never used, and the ore broken down in 1908, much of it of good quality, is still stored in the bins. In 1913 there was organized the Black Hills Tungsten Mining & Milling Co., which erected a small plant on its claims about three miles east of Hill City, and started concentrating ore in September 1913. During the first month of production the Company produced \$3000 worth of tungsten concentrate. The Company has erected shaft-houses, a power-plant, and other improvements, and its activities will be watched with much interest by those interested in the development of Black Hills mineral resources.

All tungsten deposits of any promise occur in well defined quartz veins, similar in character to the tin veins. They are all situated north or east of Hill City, with the exception of the claim of the Reinbold Metallurgical Co. on Sunday gulch, which is situated about five miles southeast of Hill City. The more prominent claims carry wolframite as the chief tungsten mineral. Scheelite, yellow, green, or brown in color, occurs both as a primary and secondary mineral in most veins. Huebnerite is the chief mineral on the Reinbold claim. Ferberite occurs in the Petit claim, $\frac{1}{2}$ mile east of Hill City. Here the deposit is a typical pegmatite.

The Black Metal, Good Luck, Wolfram, and Great Wonder claims are similar in character. They are on quartz veins which are narrow (from 6 to 18 in. thick) and which usually occur in parallel sets. Thus the Wolfram claim shows four distinct veins of about parallel strike and about 10 to 12 inches in average thickness. They exhibit strong pinching and swelling along the strike, often showing swells from 18 to 36 in. through. This is also true of the veins on the other prospects. The quartz, which is the chief mineral, is of a gray pellucid character. It carries notable amounts

of muscovite, both well crystallized and sericitic material; occasional blades of albite; and small tourmaline needles along the contacts with the schists. Graphite occurs in minute flakes and often becomes quite abundant. The veins strike about north parallel to the schistosity of the rocks. In dip they also agree with the schistosity, varying from 50° to vertical. Some veins are quite persistent, and several have been traced 1000 feet.

Wolframite occurs in well crystallized bladed crystals, exhibiting a strong metallic lustre and a blue-black color. The blades are often coarse, $\frac{1}{2}$ to 1 in. thick and 6 to 8 in. wide. They are frequently grouped in aggregates, and some groups 12 to 15 inches in diameter were noted. In some cases the distribution of the wolframite seems to be fairly uniform, in others it is spasmodic and pockety. The value of tungsten ore, however, and its ease of concentration should entitle these deposits to a careful sampling, which will undoubtedly prove that several others are of economic value. Cassiterite occurs in the wolframite veins north of Hill City, but apparently is absent in those east of Hill City. If concentrating tests should prove it to be present, it could readily be eliminated by an electromagnetic separation of the concentrates.

No tungsten ore has been produced in the Southern Hills, with the exception noted, except about 100 tons which was shipped to Germany in 1906. What has been said as to the future of the tin deposits also applies here. A custom mill would undoubtedly be a great stimulus to tungsten mining. Careful sampling would probably show that several of the deposits could support an independent plant of small capacity.

Lithia Deposits

The lithia deposits have been mined somewhat intermittently since 1900, and for the last five or six years have been the chief source of lithia in North America. They have been described lately in some detail,⁴ and no elaborate description will be attempted here. The deposits occur in pegmatites, the more promising occurring in the vicinity of Keystone. The important lithia minerals, with their composition and theoretical lithia content, are as follows:

| | Per cent. |
|---|------------|
| Amblygonite, $\text{Li}(\text{AlF})\text{PO}_4$ | 10.1 |
| Lithiophyllite-Triphylite, $\text{Li}(\text{FeMn})\text{PO}_4$ | 9.5 |
| Spodumene, $\text{LiAl}(\text{SiO}_3)_2$ | 8.4 |
| Lepidolite, $(\text{LiKNa})_2[\text{Al}(\text{OH.F})]\text{Si}_2\text{O}_6$ | 4.2 to 4.4 |

Spodumene was the first lithia mineral mined, and a total of about 1400 tons was produced. This mineral is present in a great number of pegmatites, and often

*Mining and Scientific Press, April 11, 1914.

⁴Ziegler, Victor, "The Lithia Deposits of the Black Hills," Eng. and Min. Jour., Dec. 6, 1913.

WOLFRAM TUNGSTEN MINE, NEAR HILL CITY, SOUTH DAKOTA.

in abundance. When present it is not sporadic in occurrence, but is usually evenly distributed through the pegmatites, although it favors the central zones. The crystals are often of enormous size. In the Etta mine, where they are best exposed both in the open-cut and in the tunnel, they frequently attain a diameter of three to four feet and a length of 30. The largest 'log' so far found was 42 ft. long and of 5 ft. 4 in. maximum diameter. This one log alone would yield 90 tons of spodumene. The crystals are not definitely oriented, but lie like a huge pile of logs penetrating the pegmatite in all directions. The Hugo, Wood Tin, Dyke Lode, Bull Con, and Swanzy claims, near Keystone, show spodumene in as great abundance and in as large logs on the surface as the Etta. On weathering, the spodumene loses lithia and decomposes into

a silvery or fibrous mass of a dull to silky lustre, which finally disintegrates into a loose mass of minute fibres and needles. No spodumene is mined at present.

The amblygonite occurs in nodules often of great size, but restricted in occurrence to shoots and pockets in the pegmatites. Individual nodules 1000 lb. in weight are common. The masses are white in color, fairly heavy (sp. gr. 3.2), have poor cleavage and a vitreous lustre. The Hugo, Peerless, and Bob Ingersoll mines near Keystone have been the most active producers, while the Beecher (Bond) mine near Custer, the Tin Queen near Oreville, and the Nichols mine, near Hayward, have produced smaller amounts. The Hugo mine is actively worked at present by open-cut methods.

Lithiophyllite occurs in disseminated nodules much like amblygonite, but the nodules are of smaller size and are more regular in occurrence and distribution. They are brown to brownish black in color, possess poor cleavage, are fairly hard and heavy. They frequently coated with a deep purple-red alteration

OPEN CUT, HUGO MINE. EVERYTHING BETWEEN THE WALLS OF THE CUT AND THE TWO CROSSES IS AMBLYGONITE.

CROSS-SECTION OF SPODUMENE LOG, ETTA MINE.

product—purpurite, a phosphate of iron and manganese. A number of pegmatites carry this mineral, in fact it is almost universally present. The Lost Bonanza (now Mica King) and the Dyke Lode have produced about 100 tons at various times. It will probably take the place of amblygonite when these deposits are exhausted.

Lepidolite is quite widely distributed, but important only at the Peerless and Bob Ingersoll mines. It is green, lavender, purple, colorless, or brown in color. A mass of purple lepidolite 5 by 6 by 2½ ft. is exposed in the Bob Ingersoll mine. The lepidolite at the Peerless mine is green in color. Micaceous aggregates two to three feet in diameter are common in both mines. None has been produced as a source of lithia. The total production of lithia minerals up to September 1913 and the approximate value are as follows:

| | Tons. | Value. |
|----------------------|-------|-----------|
| Spodumene | 1400 | \$ 30,000 |
| Amblygonite | 2800 | 110,000 |
| Lithiophyllite | 100 | 3,000 |
| Total | | \$143,000 |

Columbite-Tantalite

The tantalate and niobate of iron are only of importance in pegmatite about Keystone. Here they occur in the Etta, Bob Ingersoll, Peerless, Hugo, and in lesser amounts in a number of other claims. These minerals usually occur in irregular shoots or pockets consisting of aggregates of muscovite, lamellar albite, and quartz. The columbite is in small tabular crystals of iron-black color, and a dull metallic lustre, usually enclosed in the albite. The crystals average less than an inch in diameter, but occasional rich streaks are found showing crystals 6 to 8 in. wide. The crystals are usually deeply striated.

Aggregates weighing several hundred pounds have been found at several claims such as the Hugo, Peerless, and Etta, while a mass over 2000 lb. in weight was found at the Bob Ingersoll claim.⁵ The niobium constant in 25 specimens analyzed, varied from 3.57 to 57.32%, while the tantalum varied from 10.93 to 82.23%.⁶ These minerals are mined only incidentally as by-products. Probably two tons of picked columbite are at present held by several miners near Keystone.

Miscellaneous

Uranium minerals, such as uraninite, torbernite, and autunite, occur in a number of pegmatites, but apparently nowhere in abundance. Bismuth minerals, as native bismuth, bismuthinite, and tetradyomite, occur. Especially interesting is the occurrence of such minerals in ladder veins in a pegmatite on the Cobalt claim near Bismuth. There is not enough ore to be of importance. Beryl is quite common in large-sized masses

in a number of pegmatites near Keystone, and could be produced quite cheaply should a market arise. That this is likely is shown by the increasing interest in methods for the cheap extraction of beryllium. Feldspar could also be produced at low cost from a great number of pegmatites. So far the markets are in the East and the demand is readily met by producers in Pennsylvania, Maine, and New Hampshire. Apatite, together with other phosphates, might be incidentally recovered and would probably find a ready market for use as a fertilizer. Rose quartz of fine depth of color occurs in several pegmatites. It has been mined to some extent, and found of use as a semi-precious stone. The only important producer has been Scott's claim, near Custer. Appreciable percentages of monazite are reported from placers near Harney Peak.

Ore Treatment at the Champion Reef Mine, India

The following notes are from the annual report of the superintendent, Henry J. Gifford, and cover the general work done during the period ended September 30, 1913:

| | |
|---|---------|
| 'Rock' extracted from the mine, tons..... | 277,336 |
| Waste sorted out, tons | 56,825 |
| Ore milled, tons | 220,511 |
| Stamps working, average | 140.3 |
| Gold by amalgamation, fine ounces..... | 95,756 |
| Recovery by amalgamation, per cent..... | 78.8 |

The pulp leaving the batteries assayed \$2.32 per ton. It has been decided to install a classifying plant and two tube-mills, in order to separate and grind the coarse portion of the pulp. This will increase the work for the filter plant, which is of sufficient capacity to handle the extra quantity.

No. 1 cyanide plant, with the addition of a Butters vacuum-filter, has treated nearly all of the sand and slime produced by the stamp-mill, in addition to 23,843 tons of accumulated slime. The filter-plant has done excellent work, and the average residue from 40,715 tons of slime treated was 16c. per ton. Results at the two plants were as follows:

| | Sand. | Slime. |
|--|---------|--------|
| Material treated, tons | 197,685 | 40,715 |
| Before treatment, per ton..... | \$2.40 | \$1.52 |
| After treatment, per ton | \$0.88 | \$0.16 |
| Recovery, per cent | 62.6 | 88.9 |
| Cyanide consumption, pounds per ton..... | 0.661 | 0.730 |
| Zinc consumption, pounds per ton..... | 0.092 | 0.092 |

No. 2 cyanide plant treated 101,187 tons of old sand and slime, averaging \$2.76 per ton, with a recovery of 49.4%. The chemical consumption was 0.614 lb. of cyanide and 0.084 lb. of zinc per ton treated. Reserves of old tailing amount to 275,280 tons. Total returns from the mill and cyanide works was worth \$2,528,000.

Copper concentrate produced in December by the Elmore vacuum plant at the Sulitjelma mine, Norway, amounted to 620 tons.

Slime Treatment at Broken Hill

*Among Broken Hill's metallurgical achievements of the past year is the successful establishment of the 'Horwood' process for the separation of the constituent metals contained in slime (the invention of E. J. Horwood), and this was accomplished at the works of the Zinc Corporation at Broken Hill, where a plant having a capacity of about 500 tons per week has been in regular operation for about six months, treating current and accumulated dump slimes.

The slime is derived from the material being treated in the main flotation plant, being the finest portion of the floated sulphides—too fine for separation by ordinary concentration. This material was formerly sold for shipment to Europe, but being a mixture of both zinc and lead sulphides, is too rich in lead and poor in zinc to command a satisfactory price from the buyers of zinc concentrate, much of the combined lead and silver being lost in the course of roasting and distilling, and owing to the high zinc content the material is not acceptable to buyers of lead concentrate by reason of the high cost of smelting such refractory material, apart from the question of the sacrifice of the zinc such a sale would involve.

The importance of separating this material into two products, one suitable for zinc distillation, and another for sale to lead smelters—was recognized by the Zinc Corporation; and as the Horwood process had given satisfactory results on a small scale, it was decided to exploit the process on a larger scale, and this was done, first by sending 100 tons of slime to be roasted at Ballarat, and subsequently separating the material in the Corporation's experimental flotation plant at Broken Hill, and secondly, by erecting at the Zinc Corporation works a full-sized unit, including the requisite roaster as an adjunct of the treatment plant.

This plant comprises, first, the requisite receiving tanks for the slime (which is pumped in a 4-in. pipe from the dump or gravitates from the treatment plant), and a 7-ton filter-press in which the slime is dewatered and washed for the removal of soluble salts, which latter operation has a most important bearing on the subsequent treatment, enabling, as it does, the separation to be effected with a much lighter roast, and at the same time causing the silver content to follow the lead. The value of this feature is recognized when it is remembered that under the ordinary lead smelting contract the silver is paid for in full, whereas the silver in the zinc concentrate is subject to heavy deductions.

After the washing, compressed air is turned on for a short time to drive off further water before opening the press, and this permits the cakes to be discharged sufficiently dry to crumble to a large extent on dropping through the grizzly bars set under the

press. Belt conveyors deliver the material to an elevated storage bin, at the bottom of which is a triple-screw automatic feeder regulating the feed to the roaster.

The roaster is of the Edwards duplex type, with 12 panels and 48 rabbles, measuring 102 ft. long by 14 ft. wide. Three small fireboxes on each side furnish the necessary extraneous heat, but as the ore generates heat while being roasted, the fuel consumption is very small, as will be understood when it is stated that the operation does not require the material to even glow, so low can the temperature be kept. The requisite draft is afforded by a small fan which gives absolute control under every possible condition of the atmosphere.

The roasted ore is automatically conveyed to the receiving tank constituting the main storage for the solution used in the subsequent flotation process. This tank is built at such a level that any leakage from the flotation plant will gravitate to the storage tank, where the slime is kept in suspension by slowly revolving arms.

A centrifugal pump takes the pulp from this tank and delivers it to the flotation plant, where the zinc content is floated and recovered as a high-grade zinc concentrate, low in silver and lead, while the lead and most of the silver, having been deadened to flotation by the roasting, remain unfloated and are recovered as a lead smelting product rich in silver.

Typical actual plant results of the process are as follows:

| | Zinc, % | Lead, % | Silver, oz. |
|-------------------------------------|------------|------------|----------------|
| Feed to roaster | 40.4 | 14.6 | 21.4 |
| is divided into— | | | |
| Zinc concentrate assaying | 48.7 | 5.2 | 11.6 |
| and— | | | |
| Lead residue containing | 10.2 | 44.2 | 54.6 |

The grade of the lead is dependent on the amount of gangue present in the original feed.

The separate products gravitate to tanks connected with the filter-presses which promptly remove the solution and enable the products to be despatched to the seaboard without further handling or delay.

The advantage of this process, more especially in regard to material derived wholly or partly from dumps, lies in the fact that the zinc is selectively floated and not the lead. When slime is dumped, the lead content rapidly oxidizes, though the zinc is very slightly affected, and while only a very incomplete selective flotation of the lead can be effected in the case of dump slime, much more of the lead can be floated if this be done simultaneously with the easily floatable zinc, owing to the clots assisting in the flotation of the feebly floatable lead.

A further inherent advantage in preferential floating of the zinc is that the surfaces of the particles of

zinc sulphide which have been tarnished by oxidation are instantly brightened on immersion in acid solutions, whereas the acid has no effect on the oxidized coating of the leady particles—the importance of this feature as emphasizing the advantages of preferentially floating the zinc will be realized when it is remembered that bright surfaces are essential to a successful flotation.

It follows that higher recoveries of the lead and silver can be obtained from material containing dump slime by first floating both the sulphides, when the maximum possible flotation of semi-oxidized lead and silver can also be obtained, and afterward submitting the mixed concentrate to a preferential zinc flotation process, than is possible if the material be first submitted to a lead selective process. In addition, the grade of the zinc concentrate will be much higher in the former case than in the latter, owing to the fact that after applying the lead selective process to the material a considerable quantity of the feebly floatable leady particles will be floated when the subsequent flotation of the zinc is being effected, the readily floated bright zinc particles mopping up much of the tarnished feebly floatable leady particles, and reducing the grade and consequent value of the zinc concentrate, while sacrificing lead and silver for which very small payments are made when accompanying a zinc.

This process having been successfully tried out and established on a large scale on Broken Hill slime, there is every reason to expect still greater success on such complex pyritic sulphides as occur so abundantly in Tasmania, as both the laboratory tests and the tests made in the experimental plant in Victoria, where the Horwood process was first tried on a working scale, showed the Tasmanian ores to be more easily treated than Broken Hill slimes.

Tests made on Tasmanian ores show that 85 to 90% of the zinc can be recovered as a high-grade zinc concentrate, assaying 57 to 58% zinc, while the same percentage of the lead contents can be recovered in a separate product along with the iron contents of the ore, in a form which makes the material practically self-fluxing.

Production of Explosives in 1912

By ALBERT H. FAY

*The total output in the United States was 489,393,131 lb., equal to 244,696 short tons. The quantity used may be classified as follows:

| | Coal mining, pounds. | Railway con- struction, etc., pounds. | Other purposes, pounds. |
|------------------------|----------------------------|---|-------------------------------|
| Black blasting powder | 187,090,995 | 18,533,000 | 24,669,374 |
| High explosives | 20,903,430 | 89,703,081 | 123,862,981 |
| Permissible explosives | 18,150,618 | 4,668,399 | 1,811,253 |

There was 534,466,580 short tons of coal mined in 1912, consuming 226,142,043 lb. of explosives, or 2.36

*Abstract from Technical Paper 69, Bureau of Mines, Washington.

tons per pound used. The fatalities due to explosives were 133, or 0.59 per 1,000,000 lb. used.

The following table shows the amount of explosives, excluding exports, manufactured and used in the various states in 1912:

| | Black blast- ing powder, pounds. | High explosives other than permissible, pounds. | Per- missible explosives, pounds. |
|----------------------|--|--|--|
| Alabama | 5,277,375 | 4,542,192 | 3,856,130 |

Forty milligrams of radium bromide was sold in December by the Radium Hill Co., whose laboratory is at Sydney, New South Wales. The mine is in South Australia.

Geology of the Chisana District, Alaska

The bedrock of the district is shale and slate with some intrusives. It has long been known that this region was mineralized (see *Bulletin 417* of the U. S. Geological Survey), and both copper and gold-bearing lodes have been long known to occur in this general region. The shallow gravels are without doubt of post-Glacial age, but some of the deeper and bench

naces and cyaniding, treated 93,674 tons of ore worth \$17.70 per ton. The Cote d'Or reduction works of 50 stamps and six filter-presses, including wet and dry crushing, roasting, cyaniding, and filter-pressing, treated 54,773 tons of ore worth \$9.04 per ton.

Filling Ore Sacks

By T. R. ARCHBOLD

*Filling ore sacks by hand, when a considerable number have to be done, is a slow process, and expensive in labor, and the machine described and illustrated was designed with a view to reducing the number of men employed and making the work as nearly automatic as possible.

It consist of two parts. A drum (1) divided into six compartments, each compartment holding exactly a sack of ore, revolves in a hopper (2) which is divided in the middle, allowing three compartments to empty out of each side into the sacks. The diagram will make the principle of operation clear. The machine as made will fill two sacks at a time, but, of

course, the drum could be made longer, and three or more filled. The ore passes from the ore-bin through a chute which must fit snugly on the circumference of the drum. Each compartment of the drum is half closed, and the edge of the portion closing it is reinforced with a knife-edge (*a*) of hard steel. A lever for turning barrel is fixed on a ratchet. As the lever is depressed, the full compartment empties into the sacks and the next two compartments fill. The bottoms of the sacks rest on a small car, running on a slightly inclined track. The sacks are slipped off the hopper and the car is released by pulling the catch in the middle, when it runs a few feet to where the sacks are being sewn.

The machine has given every satisfaction, and I think that 360 sacks per hour can be filled with three men, a task which used to take 15 men when working with shovels. It is an advantage to know that all sacks contain exactly the same quantity of ore. The only disadvantages I have found are: (1) if the ore has been some time in the bin during wet weather, it packs and delays the work, but this, after all, is the case with all bins; and (2) it will not take large stones, as they jamb between the chute and the drum. The knife-edge obviates this to a great extent, but I found it necessary to put a 'grizzly' above the bin, with bars 1.3 in. apart, and have had no trouble since. In any case, it is not advisable to put large stones in the sacks, because they are almost sure to tear them in transit.

*Abstract from *Bulletin 113* of the Institution of Mining and Metallurgy.

TRAILS TO CHISANA (AFTER CAIRNES).

gravels may be older. It appears that the best hope for extensive gravel deposits lies in the finding of pre-Glacial gravels. The northern limit of glaciation lies about 20 miles to the north of this district, near where the Chisana emerges from the mountains. The southern boundary of an area of schists and intrusive granites lies about 50 miles north of Johnson creek. These rocks are known to be locally mineralized, and are of the same types as those found in most of the Yukon camps. There has been but little prospecting in this region, largely because of its inaccessibility. It is certainly worthy of careful attention on the part of the prospector. An excellent report upon the district, by D. Cairnes of the Canadian Geological Survey was published and noted some weeks ago.

A subsidiary company, called the Nechi Mines (Colombia), Limited, is to be formed by the Oroville Dredging Co. to take over 400 acres of ground recently acquired in Colombia. It is proposed to construct a 9-ft. dredge of 40,000 cu. yd. weekly capacity, at a cost of £36,000. The new Company is to have a capital of £140,000, divided into 140,000 25% preference shares of 10s. each, and 14,000 ordinary shares of 10s. each.

Mill work at the Ashanti Goldfields mines, West Africa, in the year ended June 30, 1913, was as follows: central plant of seven ball-mills, roasting fur-

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Puzzle in Sulphide Enrichment

The Editor:

Sir—By the oxidation of pyrite and chalcopyrite, sulphuric acid and ferric and cupric sulphate are formed. Pyrrhotite, alabandite, and sphalerite when brought in contact with acids generate hydrogen sulphide gas, which has been supposed to precipitate secondary sulphides. Since the acidity of descending solutions decreases with depth, the generation of hydrogen sulphide gas may reasonably be supposed to be confined to the zone of oxidation where sulphuric acid, ferric and cupric sulphate are generally present. It is interesting to note, however, the fact pointed out by F. F. Grout in *Economic Geology* (Vol. 8, p. 415) that in a mixed solution of cupric and ferric sulphates, pyrrhotite and sphalerite cease to be active generators of hydrogen sulphide gas, while alabandite does not.

In an experiment, ferric and cupric sulphate solutions were put in three test-tubes, and in tube A pyrrhotite, in tube B sphalerite, and in tube C alabandite were placed and set aside for a week. No change was observed in tubes A and B. In tube C, in which alabandite was placed, it was noticed that copper sulphide was precipitated and that the pyrite and chalcopyrite were coated with chalcocite and bornite respectively.

Although alabandite has recently been found to be intimately associated with galena, yet it is known to be rather of rare occurrence in sulphide ore deposits, and does not seem to play an important part in the rôle of secondary sulphide enrichment. The experimental fact appears to show that the presence of cupric sulphate inhibits the generation of hydrogen sulphide gas, and it is difficult to see why hydrogen sulphide gas causes precipitation of secondary sulphide in the zone of oxidation, unless alabandite is present.

Relative Efficiency of Sodium and Potassium Cyanide

The Editor:

Sir—In studying Mr. Butters' valuable figures on relative efficiency of the two cyanides, published in the *Mining and Scientific Press*, March 28, I am not able to reconcile the figures with his conclusions as to relative difference of cost. In order to derive the additional cost due to using sodium cyanide, he evidently intends to get the additional cost of an equal amount used, on the relative costs per pound of 22c. and 17c., respectively, and add to this the cost of half a pound

of sodium cyanide (presumably the excess shown by the figures, though this is really 0.47 lb.). He therefore multiplies 30% by 17 and obtains 5c. Should this not also be multiplied by 2.17, the amount of potassium cyanide being compared, making 11c. instead of 5c., and making the loss per ton of ore, due to using sodium cyanide, equal between 21 and 22c. instead of 16c. as given by him? Perhaps I am mistaken. I hesitate to question figures by such an eminent authority, and if mistaken, should like to have the matter explained for my benefit. It seems to me, however, that my contention is borne out by simply comparing the totals of the amounts used per ton each multiplied by the prices given per pound, namely, 2.64 lb. at 22c. = 58.3c.; 2.17 lb. at 17c. = 37c.; the difference being 21c. per ton in favor of potassium cyanide. If this is correct, what is the need of the complex method used of getting this comparison? Indeed, in using sodium cyanide, I always treat it as 130% potassium cyanide for practical purposes, using 0.77 lb. of it in place of 1 lb. of potassium cyanide called for in regular tests, the standardizing being done with pure potassium cyanide and deriving the loss in terms of 100% potassium cyanide. This is the unit on which the price is based, and forms a convenient unit throughout. It is like the relative merits of the gold and silver monetary standard. There must be some standard, but it matters little which is made the standard.

Regarding relative merits of the two, my experience has been that the sodium salt should never be adopted until the ore has been tested in a run with each salt, other conditions being kept the same. I never have seen a case where it gave better results. I have alternated in certain cases from one to the other with no apparent difference in extractions, and in one notable case, where the mistake was made of ordering a carload of the sodium cyanide in starting a new plant, it was impossible to reach, as I remember, within 10% of the extractions indicated in the experimental mill, where potassium cyanide was used, until a supply of the potassium salt was obtained on a rush order. The extractions immediately responded by jumping up to where they belonged. This was at the plant of the Rossland Power Co. at Trail, B. C., working on tailing from concentration of Rossland ore. The physical conditions governing settling had to be observed very closely, owing to the presence of much hydrated slime, settling action prior to agitation having had to be carefully avoided. No lime could be added to the ore before extraction was obtained, without reducing it by 20% or more. In laboratory tests with the two salts there seemed to be a slightly greater settling with the sodium cyanide, but it was so slight that it hardly warranted us in assuming that as the cause of non-extraction. Is it not a fact generally recognized among chemists that the potassium salts are as a rule more active chemically than the sodium? In nearly all chemical works where reference is made to the use of one or the other, in a given case the potassium salt is.
